Report U. S. F. C. 1902. (10 face page 1.)

PIVERS ISLAND AND LABORATORY.

BEAUFORT LABORATORY-EXTERIOR VIEW.

REPORT

OF THE

UNITED STATES COMMISSIONER OF FISH AND FISHERIES

FOR THE

FISCAL YEAR ENDING JUNE 30, 1902.

I have the honor to submit a report covering the fish-cultural work and scientific and statistical investigations of the United States Commission of Fish and Fisheries for the fiscal year ending June 30, 1902, together with the detailed reports of the assistants in charge of its different divisions.

PROPAGATION OF FOOD-FISHES.

Natural conditions governing the collection of eggs were generally very favorable at all points where operations were carried on, and increased appropriations made it possible to take advantage of these conditions. The Commission was therefore enabled to keep up its record and show an increased output of nearly all of the species handled, and in the aggregate there were distributed over 1,495,500,000 fish and eggs, or 321,700,000 more than last year. Of these, 99 per cent were in the interests of the commercial fisheries and 1 per cent, or 14,900,000, were game fishes. Popular interest in the Commission and wider knowledge of its functions are shown by the increasing number of applications for fish to stock interior waters, 3,814 having been received, or 25 per cent more than the previous year.

The propagation of quinnat salmon was carried on in California, Oregon, and Washington, at 12 stations, including several collecting camps, and the season's work was considered very satisfactory. The runs of fish in the various streams were in most cases good, and over 56,000,000 eggs were collected. 29,300,000 fry and fingerlings were hatched and planted and 17,480,000 eggs were transferred to the California State Commission. As far as possible fry were held and fed during the winter and planted when about $2\frac{1}{2}$ inches long, but lack of room and other facilities prevented pursuing this policy to its full extent. A few silver-salmon eggs were taken on a tributary of Rogue River, Oregon, and steelhead-trout eggs were obtained at the same

F. C. 1902-1

1

point and at the Baker Lake Station in Washington. The collection of steelhead eggs was hampered by unfavorable weather and scarcity of fish. At Baker Lake 3,694,000 blueback-salmon eggs were taken and hatched with a small percentage of loss, and the fry were planted in the lake.

Over 41,000,000 lake-trout eggs were obtained from commercial fishermen in Lake Superior and Lake Michigan; of these, 5,000,000 were assigned to various State commissions and other applicants, and the remainder hatched by the Commission, the fry—except some 700,000—being planted in the Great Lakes.

In Lake Erie the number of white-fish eggs secured from fishermen exceeded any previous record, the hatchery at Put-in Bay at one time being so crowded that they were retained in temporary devices. The facilities for holding the white-fish in pens were increased, but, owing to unpropitious weather, not many eggs were obtained from fish thus held at Lake Erie points, though at the collecting stations on the Detroit River the results were very successful. The total take of white-fish eggs amounted to 701,900,000, of which 111,000,000 were assigned to State commissions and others and the balance hatched at different stations of the Commission, whence the fry were planted in the lakes. The quality of the fry was unusually good.

Although April was cold and unfavorable, 437,000,000 pike-perch eggs were taken in Lake Erie, but the weather conditions were such that the percentage of fry was comparatively small. At Swanton, Vt., 113,000,000 eggs of this species were also obtained. No lake herring were taken, as the work was interrupted by ice before any spawning fish were found.

On the New England coast 338,120,000 cod eggs were collected and hatched at Woods Hole and Gloucester, Mass. Those from the brood fish taken off Nantucket Shoals and held at Woods Hole were of exceptionally good quality. Cod were scarce on the Maine coast, and the number of eggs from this source was not large. From Plymouth fishermen, however, the supply was good.

The flat-fish work was more successful than in the preceding year, both in the collection of eggs, which amounted to 194,000,000, and in the hatching of fry.

The collection of lobster eggs was also more satisfactory, though some of the territory in Massachusetts formerly depended on was abandoned. In Maine, however, egg-bearing lobsters were abundant. Eggs from all sources numbered 103,898,000, which, except for 5,000,000 devoted to experiments in hatching and rearing, were hatched at the New England stations and yielded \$1,000,000 fry.

The runs of shad in the rivers where the Commission operates were small, owing to the late spring, and consequently the take of eggs shows a falling off, the station on the Potomac being the only one where there was an increase, while on the Delaware, where the collections have usually been large, there was a great decrease. 141,239,000 eggs were secured from all points and 107,000,000 fry were hatched and planted. Considerable consignments were sent to rivers north and south, where the shad runs have been diminishing in recent years.

The propagation of the trouts, basses, and other fish appropriate for interior waters has been satisfactorily continued, and these species supplied to applicants in all parts of the country. The collections of wild fishes from overflowed lands along the Mississippi River continued throughout the summer, and large numbers of bass and other native fishes were saved and distributed. On the Illinois River this work was curtailed by the excessive heat, which caused the death of many fishes in the shallow ponds.

In continuation of the policy of acclimatizing certain species in sections of the country to which they are not indigenous, steelhead and grayling eggs were brought from the West to be hatched at eastern stations, and white-fish, lake-trout, and brook-trout eggs were sent to the Pacific coast, where they were hatched and planted. Landlocked salmon eggs from Maine were sent to various places as far west as Utah.

Twenty-nine species of fish and one crustacean have been handled during the fiscal year, and in the following tables and in the reports of station superintendents are shown the results attained in hatching the eggs and the disposition of the product.

Summary of distribution.

RAILROAD TRANSPORTATION.

The cars of the Commission while distributing fishes during the fiscal year have traveled 95,259 miles, and detached messengers 199,944 miles. The work of distribution has been greatly facilitated by the free transportation furnished through the courtesy of the following railroads:

| Name of railroad. | Cars. | Messen- gers. | Name of railroad. | Cars. | Messen- gers. |

BIOLOGICAL INQUIRIES.

The experiments which have been carried on for several years at Lynnhaven, Va., to perfect a method by which oysters can be fattened and improved in flavor and food value are meeting with encouraging success. Means have been found to supply proper food in sufficient quantity and in a systematic manner, and it is believed in another season it can be demonstrated that oysters can be fattened for market by simple economical means. This will make the industry far more profitable than the present method of allowing the oysters to grow under natural conditions, which is always uncertain and often will not give the best results.

Successful results are hoped for from the experimental work carried on in Florida in raising sponges from cuttings. It is desired to discover methods which will be available for the practical sponge-grower and which will permit the cultivation of sponges systematically and assure the grower of regular marketable crops. As Florida can now supply only about half the demand of this country, and as the natural sponge-grounds are rapidly becoming depleted, the undertaking is watched with interest by prominent dealers.

A systematic investigation of the carp in the Great Lakes, where this species is very abundant, was undertaken on account of the disfavor in which it is held by many persons. Attention was given to the food and feeding of the carp, its relation to other fishes, and its food and market value. It is probable that the prejudice against this fish comes from a misapprehension and may be removed with a fuller knowledge of the facts. Much information on the subject has been obtained, and the inquiries will be continued another season.

The supposed destruction of fish and apparatus by sea lions has caused apprehension to the fishery interests of the Pacific coast, and in some localities systematic efforts have been made to kill off the herds. A diversity of opinion has existed as to the advisability of this course, for while the fishermen claim that great damage was done, this was

11

hardly substantiated by reliable data, and the extermination of the herds met with opposition in many quarters. The Commission was finally asked by the California authorities to make an investigation of the food and feeding habits of the sea lions with a view to determining the point at issue. This was accordingly undertaken by an agent of this office, assisted by a representative from both the California board of fish commissioners and the California Academy of Sciences, and was carried on during July and August. As thorough an inquiry as practicable was made, from which it appears that the sea lions did not do much damage except at the mouth of the Columbia River, but further study of some aspects of the case will be necessary before a definite conclusion can be reached.

At the request of oyster-growers of Tuckerton, N. J., a representative of the Commission was detailed to investigate the destruction of oyster beds in that vicinity by drum-fish. These fish feed on the seed oysters, which are the thin-shelled eastern forms, and cause enormous losses, many extensive beds being practically depleted. In one case, where some 20,000 bushels of oysters had been planted, an examination showed that over 80 per cent had been destroyed. Various expedients have been tried or suggested without much success, and it would seem that it will be necessary to use heavy-shelled oysters, which are strong enough to resist the drum-fish, for seed, rather than the thinshelled ones. The former, however, at this particular locality do not attain so satisfactory a growth.

The biological survey of the Great Lakes has been continued, the work still being confined to Lake Erie with headquarters at the station of the Commission at Put-in Bay. Special attention was given to the white-fish, wall-eyed pike, carp, and sturgeon.

The investigations of the fisheries of the Territory of Hawaii, called for by act of Congress, were partially completed during the summer of 1901, most of the islands being visited, the fishery methods and laws studied, a statistical canvass made, and a large and interesting collection of fishes obtained. A preliminary report was made to the President in July, 1902, and by him submitted to Congress. As stated elsewhere, the investigation of the deeper waters around the islands is now being continued by means of the steamer *Albatross*.

Among other investigations may be mentioned the continuation of the biological study of the quinnat salmon in California, a further inquiry as to the results of introducing new species into certain lakes in Idaho and Utah, an inquiry into the geographical distribution of trout and salmon in the waters of Maine, and biological investigations of certain waters of New York and New Jersey.

The subject of the diseases of fishes has received considerable attention, the time of one assistant being entirely devoted thereto. Mortality from causes little understood in the Government hatcheries and private establishments has always been a source of embarrassment and loss. These studies have been made at a number of places and under various conditions, and it is hoped they will result in rendering it possible to stamp out disease, or, better still, prevent its appearance.

The laboratories at Woods Hole and Beaufort, which have been open as usual during the season, have been utilized by a number of trained investigators, who are attracted by the facilities offered for biological research. The investigations carried on have direct bearing on the various problems related to the fisheries and are exceedingly valuable to the Commission in the performance of its functions.

In the laboratory at Washington studies have been made of various collections of fishes and of particular species, reports prepared, and much work of a miscellaneous character accomplished.

STATISTICAL INQUIRIES.

The principal statistical canvass undertaken was that of the Middle Atlantic States, and at the close of the fiscal year it was still in progress. Besides this, the lobster fishery and several inquiries relating to minor or local fisheries were covered.

At Boston and Gloucester, during the calendar year 1901, there were landed 151,165,191 pounds of fishery products, valued at \$4,245,951. These figures are somewhat less than in the preceding year, both in quantity and value, both ports participating in the decrease.

An inquiry prosecuted in the State of Utah developed that a considerable fishing industry, amounting to over 1,000,000 pounds and nearly \$50,000, is carried on in that State, the principal part of the catch being taken from Utah Lake and consisting mainly of carp, trout, and black bass. It is not possible to show the entire quantity taken, for here, as in other interior waters, much of the fishing is by sportsmen or for the personal use of the fishermen and is not reported.

In the season of 1901 a canvass of the lobster fishery of the Atlantic coast States was made, and interesting comparisons of the value of the industry for the preceding ten years will be found on pp. 156–158. This inquiry, which covered the calendar year 1900, showed a total investment of \$1,668,000 and that 4,348 persons were employed. While lobster fishing is carried on to some extent from New York and New Jersey, it is chiefly confined to the New England States, Maine having far the largest interest, followed by Massachusetts. The total yield was 15,767,700 pounds, having a first value of \$1,390,500.

In the report of the Division of Statistics, on pp. 154–155, will be found notes on salmon fishing with hand apparatus in several localities on the Pacific coast. This method of capture has achieved some commercial importance during the last few years, besides being in vogue with anglers. There are also given in the report the results of some inquiries respecting the trade in fur-seal skins in London.

13

NEW STATIONS.

Work was begun on the biological station near Beaufort, N. C., the latter part of July, 1901, and it is now practically completed and in operation. It was desired to afford this establishment every facility

for carrying on marine biological research, for which it is admirably located, and its appointments and equipment, while plain, are substantial and as complete as possible.

The main building is a 2-story frame structure 70 by 42 feet, with

LABORATORY INTERIOR, BEAUFORT.

OBSERVATION TANK, BEAUFORT LABORATORY.

15

two wings each 51^s/₃ by 17^s/₃ feet, and contains a laboratory, aquarium, office, 12 bedrooms, commodious halls, 2 bathrooms, and storerooms. In front is a portico with a balcony, and around the sides is a veranda. In the center of the large aquaria hall are two oval tanks, 12 by 8 feet and 3 feet deep, constructed of white cedar and finished with cement. Along the north wall, in front of each window, are placed large aquaria with tidal boxes between. The room also contains a tank-table and saurian tank, three compartment hatching-tables, work-tables, and sinks. Along the north and south walls of the laboratory are compartments divided by partition shelves, each compartment being provided with a table for microscopes. Four large tank-tables, two at either end of the room, are arranged for the experimental work of the laboratory, while two long tables in the center contain lockers and shelves for the supplies. At each end are sinks. All other available space is used for show-cases.

Sixty-five feet north of the main building is the mess-house, a 14story frame structure, 36 by 33 feet, containing a dining-room, three bedrooms, kitchen, and bath. Near by is the power-house, 36 by 33 feet, in which are the boiler, pumps, dynamo, etc. All these buildings are lighted with electricity and have slate roofs. There are also a boat-house, fuel-shed, outbuildings, and a landing-pier 80 feet long. Fresh water is obtained from an artesian well 200 feet deep and a brick cistern with a capacity of 10,000 gallons. Salt and fresh water tanks are placed in towers on the wings of the main building, from which the water is distributed by pipe lines as needed.

Under the authority of an act of Congress approved June 6, 1900, correspondence was begun with a view to the selection of a site for a fish-cultural station in West Virginia, and during the fall of 1900 and the succeeding year a number of localities in different parts of the State were examined by the Commissioner personally and by agents of the Commission. A site about two-thirds of a mile from White Sulphur Springs, Greenbrier County, was finally decided upon as combining the desired requisites for both trout and bass culture. Here was found a spring flowing 1,800 gallons per minute, with a temperature of 53° in August. Below the spring several small runs, with temperatures of 65° to 70°, can be utilized, which will augment the supply by about 5,000 gallons per minute. Land was available where buildings can be advantageously erected and well adapted to the construction of ponds below the spring, and railroad facilities are good. Accordingly a tract of 25 acres was purchased June 26, 1902, and the preparation of plans was at once begun.

An item in the urgent deficiency bill approved February 14, 1902, so amended an item in the sundry civil bill approved March 3, 1901, providing for the establishment of a fish-cultural station at Tupelo, Miss., as to allow the purchase of land. The wording of the act limited the location of the station to the town of Tupelo, and a site comprising 28 acres was selected on its southeast border, where it would appear that a water supply can be obtained by artesian wells. Steps have been taken to acquire the property.

An act of Congress approved February 4, 1901, provided for a lobster hatchery on the Maine coast, and after an examination of different localities by the Commissioner and representatives of the Commission conversant with the needs of such an establishment. McKown Point, on the southwest side of Boothbay Harbor, was chosen. This is about $3\frac{1}{2}$ miles by land and about a mile by water from the town of Boothbay Harbor, Lincoln County, where there are daily boat connections with Bath and other important towns. The site selected has an area of 9 acres. It is on a rocky point with deep water close to the shore, thus insuring a good water supply by pumping even at low tide; boat landings can be advantageously constructed, and the ground lies well for a convenient arrangement of the hatchery and other buildings. Moreover, Boothbay Harbor is an excellent center for obtaining egg lobsters in quantities for artificial propagation, which is a matter of importance.

STEAMER ALBATROSS.

The salmon investigations conducted with this vessel during the summer of 1901 were carried on in southeast Alaska, and it was intended to complete the survey begun in 1897. Smallpox broke out among the crew, compelling the return of the ship earlier than was intended, but though an examination of all the new canneries in this part of the Territory was interfered with, the stream and lake work was practically completed. The vessel reached Seattle early in September. A report covering the salmon investigation for 1900 and 1901 will soon be issued, which, taken in connection with that of 1897, it is believed will give a comprehensive account of the commercial aspects of the salmon interests of Alaska.

During September and October an examination was made along the coasts of Washington, Oregon, and California, looking to the movements of salmon at sea and the results of the introduction of eastern lobsters and crabs. At the end of October the *Albatross* was in San Francisco for the purpose of refitting and making minor repairs preparatory to her next duty.

In continuation of the investigation of the Hawaiian fisheries, begun in 1901 by direction of Congress, it was decided to send the *Albatross* to those islands to study the conditions in the surrounding waters. An arrangement was made with Dr. David Starr Jordan to have general supervision of the expedition, and Dr. Charles H. Gilbert was put in immediate charge of the scientific work. The investigation was to embrace dredging and collecting in channels and on the banks about the islands, and a thorough examination of the surroundings of Kauai, the oldest of the group, of outlying reefs about the islands northwest of Kauai, and of the different fishing-banks. It is believed information of both commercial and scientific importance will be gained. The vessel sailed from San Francisco March 11, arriving at Honolulu March 24, where the investigation was at once begun and is now in progress.

On October 26, 1901, by order of the Secretary of the Navy, Commander Jefferson F. Moser, U. S. Navy, was detached from the command of the *Albatross* and was succeeded by Commander Chauncey Thomas, U. S. Navy. Commander Moser's services with this Commission covered a period of over four years and were efficient and valuable. His detachment was viewed with regret.

STEAMER FISH HAWK.

On July 3, 1901, this vessel left Gloucester City, N. J., for Woods Hole, Mass., where she was detailed for duty in connection with the laboratory until September, when she was sent to Baltimore to undergo considerable repairs. It having been determined to use her in connection with the sponge investigations on the Florida coast, she sailed from Baltimore October 8, 1901, arriving at Cedar Keys, where it was decided to establish headquarters, on the 21st. The work outlined for the vessel was to determine and plot the area of the different spongegrounds; to investigate the nature of the bottom and depth of water as affecting the growth, distribution, and abundance of marketable sponges; and to examine biologically certain areas, making as complete collections of specimens as possible. A survey covering all the sponge-grounds on the west coast of Florida, north of Tampa Bay, was continued till January 29, 1902, during which lines of soundings and dredgings, about 5 miles distant from each other, were made from shoal water out to a depth of about 10 fathoms. On completing this work the vessel proceeded to Key West, Fla., and made a series of dredgings for the purpose of determining the nature of the marine fauna in this region as bearing on the advisability of establishing a biological station at Key West, and also to ascertain the condition of the sponge-grounds in this region. During the season collections of live fishes were made for the aquarium at the Charleston Exposition. The results of these operations, though considerably retarded by bad weather, are regarded as successful, and will be enlarged on when the complete reports of the condition and resources of the Florida spongegrounds are published.

From March 17 to April 10 the *Fish Hawk* was at Charleston, S. C., moored at the Exposition grounds, where she formed an attractive feature of the exhibit of the Commission by illustrating the methods of carrying on deep-sea investigations, with the appropriate apparatus. After some repairs at Baltimore the vessel proceeded to Gloucester City, N. J., and on April 29 the usual spring shad-hatching on the Delaware was taken up and continued until the close of the fiscal year. The fish-cultural work is referred to elsewhere.

F. C. 1902-2

EXPOSITIONS.

At the close of the Pan-American Exposition at Buffalo, November 1, 1901, it was desired by those interested to have the Government exhibits sent to the South Carolina Interstate and West Indian Exposition, which was to open at Charleston, S. C., December 1. Congress at that time had provided no funds for the purpose, but with the approval of the President the heads of the Executive Departments directed that such parts of their respective exhibits as might be desired should be sent to Charleston for display there, provided that all the expenses should be borne by the exposition authorities. Accordingly. the Commission sent its entire exhibit directly from Buffalo to Charleston, where it was installed in a building constructed for the purpose. with an amount of space equal to that in Buffalo, except that the aquarium was much smaller.

By an act approved January 21, 1902, Congress appropriated \$90,000 to defray the expense of the Government exhibit. At the close of the exposition, on the 31st of May, 1902, the material was returned to Washington.

The board of directors of the Pan-American Exposition awarded commemorative diplomas to the Commission for its exhibits as follows: The collective exhibit; the aquarium; the hatching and transporting apparatus: fishing apparatus and accessories; scientific researches; products of fisheries; sponges; collection of pearls and pearl-bearing shells: reports and bulletins. The Interstate and West Indian Exposition awarded a diploma and gold medal.

By an act approved March 3, 1901, Congress appropriated \$5,250,000 for the Louisiana Purchase Exposition to be held in St. Louis in 1903. The act directed the appointment by the President of a national commission and also that the Executive Departments and bureaus, including this Commission, should take part. The Government exhibit, as usual, is to be under the direct control of a board of management consisting of a representative from each establishment participating. Mr. W. de C. Ravenel, who has represented the Commission at all the recent expositions, was designated to act in a similar capacity at St. Louis. The opening of the exposition has been deferred till 1904.

Invitations to participate in the below-mentioned expositions were received, but could not be accepted in the absence of specific authority from Congress:

- International Exposition of Hygiene, Maritime Security, and Fishing, Ostend, August-September, 1901; organized under the auspices of the Communal Administration.

- Administration. International Exhibition of Fisheries, St. Petersburg, February-March, 1902; organized by the Imperial Society of Fisheries and Fish-Culture. International Fishery Exhibition, Vienna, September 6-21, 1902, on the occa-sion of the eighth Austrian Fishery Conference. Exposition of Hydro-biology, Fish-culture, and Fishing, Moscow, March, 1903; organized by the Ichthyological Section of the Imperial Society of Acclimatation of Russia.

MISCELLANEOUS.

At Neosho, Mo., it was found advisable to obtain an addition of $3\frac{1}{2}$ acres of land in order to control the water supply from Spring Branch and to extend the pond system. This purchase was made by deed dated June 6, 1901.

Two small tracts of land were also purchased at San Marcos in order to straighten the boundary lines of the property and to obtain additional area for new ponds with land and water rights adjacent to the San Marcos River. These purchases were deeded October 2, 1901, and March 27, 1902.

The increasing work involved in the collection and distribution of adult fishes in the Mississippi River and its tributaries in connection with the operations of the Manchester, Iowa, Station has rendered the use of a steamer specially constructed for the purpose very desirable. as by this means the work can be conducted more efficiently and economically. Accordingly, under authority of an act of Congress approved March 3, 1901, a contract was entered into with Kahlke Brothers, of Rock Island, Ill., to build a two-decked, stern-wheeled river steamboat 76 feet long, 20 feet beam, with 3 feet depth of hold. On the main deck are light galvanized-iron retaining-tanks, 4 feet by 21 feet by 2 feet, for carrying fish, with pump, air-compressor, and necessary machinery for a complete circulating apparatus; on the deck above are the pilot-house and a deck-house containing four double bunks. The boat is propelled by a pair of lever engines, with a boiler 40 inches in diameter and 16 feet long. The vessel will be completed and ready for use during the coming season.

Besides the usual repairs to the steam launches and smaller vessels, to keep them in good condition, the *Shearwater* and *Senator* have been thoroughly overhauled, the hulls of both being practically rebuilt, as they were in bad condition and showed serious signs of decay.

CHANGES IN PERSONNEL.

On February 14, 1902, Mr. W. de C. Ravenel, who had been assistant in charge of the Division of Fish-culture since 1895, severed his connection with the Commission to accept an administrative position with the United States National Museum. Mr. Ravenel, entering the service in 1884 as superintendent of the St. Jerome, Md., Station, had risen through different grades, and his record has always been distinguished for efficiency and business ability. He has taken a prominent part in the exposition work of the Commission, and has been its representative on the Government Boards of Managers at all the expositions held in this country, except at Cincinnati and Chicago. At the latter exposition he was chief special agent.

PUBLICATIONS.

During the year there have been added to the library 115 books and 185 pamphlets and unbound volumes. The bound report for 1900 has been issued together with the following pamphlets:

- The Mollusca of Porto Rico, by W. H. Dall and C. T. Simpson. Bulletin for 1900. vol. 1, pp. 351-524, plates 53 to 58.
- The Brachyura and Macrura of Porto Rico, by Mary J. Rathbun. Bulletin for 1900, vol. 2, pp. 1 to 127+*129 to *137, plates 1 and 2.
- The Anomuran collections made by the Fish Hawk expedition to Porto Rico, by J. E.
- Benedict. Bulletin for 1900, vol. 2, pp. 129–148, plates 3–6. Stomatopoda of Porto Rico, by R. P. Bigelow. Bulletin for 1900, vol. 2, pp. 149–160. Report on Porto Rican Isopoda, by H. F. Moore. Bulletin for 1900, vol. 2, pp. 161– 176, plates 7-11.
- The Cirripedia collected near Porto Rico by the Fish Hawk expedition in 1898-99, by M. A. Bigelow. Bulletin for 1900, vol. 2, pp. 177-180.
- The Polychaetous Annelids of Porto Rico, by A. L. Treadwell. Bulletin for 1900.
- vol. 2, pp. 181–210. Descriptions of two new leeches from Porto Rico, by J. Percy Moore. Bulletin for 1900, vol. 2, pp. 211–222, plates 12–13. The Nemerteans of Porto Rico, by W. R. Coe. Bulletin for 1900, vol. 2, pp. 223–229.
- The Echinoderms of Porto Rico, by H. L. Clark. Bulletin for 1900, vol. 2, pp. 231-263, plates 14-17.
- The Alcyonaria of Porto Rico, by C. W. Hargitt and C. G. Rogers. Bulletin for 1900, vol. 2, pp. 265-287, plates 1-1v.
- The stony corals of Porto Rican waters, by T. Wayland Vaughan. Bulletin for 1900, vol. 2, pp. 289-320, plates 1-XXXVIII.
- Actinaria from the vicinity of Porto Rico, by J. E. Duerden. Bulletin for 1900, vol. 2, pp. 321-374, plates I-XII.
- The sponges collected in Porto Rico in 1899 by the U.S. Fish Commission steamer Fish Hawk, by H. V. Wilson. Bulletin for 1900, vol. 2, pp. 375-411.
- Dredging and other records of the U.S. Fish Commission steamer Albatross, with bibliography relative to the work of the vessel, compiled by C. H. Townsend. Report for 1900, pp. 387-562, plates I-VII.
- The French sardine industry, by H. M. Smith. Bulletin for 1901, pp. 1-26, plates 1-8.
- Biological notes, No. 2, from the biological laboratory at Woods Hole. Bulletin for 1901, pp. 27-33.
- Description of a new oceanic fish found off southern New England, by Carl H. Eigenmann. Bulletin for 1901, pp. 35-36.
- The egg and development of the conger eel, by Carl H. Eigenmann. Bulletin for 1901, pp. 37-44.
- Investigations into the history of the young squeteague, by Carl H. Eigenmann. Bulletin for 1901, pp. 45-51.
- A new isopod parasitic on the hermit crab, by Millet T. Thompson. Bulletin for 1901, pp. 53-56, plates 9-10.
- The plants of western Lake Erie, with observations on their distribution, by A. J. Pieters. Bulletin for 1901, pp. 57-79, plates 11-20.
- The Leptocephalus of the American eel and other American Leptocephali, by C. H. Eigenmann and C. H. Kennedy. Bulletin for 1901, pp. 81-92. Report of the Commissioner for the fiscal year ending June 30, 1901, by George M.
- Bowers. Report for 1901, pp. 1-170.
- Publications of the United States Commission of Fish and Fisheries available for distribution on December 1, 1901. Report for 1901, pp. 177–192. Notes on the fishes and mollusks of Lake Chautauqua, N. Y., by B. W. Evermann
- and E. L. Goldsborough. Report for 1901, pp. 169–175. The Foraminifera of Porto Rico, by James M. Flint, medical director, U. S. Navy. Bulletin for 1900, vol. 2, pp. 413–416.
- Description of a new species of blenny from Japan, by Hugh M. Smith. Bulletin for 1901, pp. 93, 94.
- List of species known to occur in the Great Lakes or their connecting waters, by Barton Warren Evermann. Bulletin for 1901, pp. 95, 96. Notes on the tagging of four thousand adult cod at Woods Hole, Mass., by Hugh M.
- Smith. Report for 1901, pp. 193-208.
- Notes on the silversides of the genus Menidia of the east coast of the United States, by W. C. Kendall. Report for 1901, pp. 241-267.

REPORT OF COMMISSIONER OF FISH AND FISHERIES.

Notes on the Scotch methods of smoking haddocks, by Hugh M. Smith, Report for 1901, pp. 269-271.

Notes on the fishes of Lake Ontario. An annotated list of the fishes known to occur in Lake Champlain and its tributary waters. An annotated list of the fishes known to occur in the St. Lawrence River. By B. W. Evermann and W. C. Kendall. Report for 1901, pp. 209–240. A report on fishes collected in Mexico and Central America, by B. W. Evermann

and E. L. Goldsborough. Bulletin for 1901, pp. 137-159.

The organic constituents of the scales of fish, by E. H. Green and R. W. Tower. Bulletin for 1901, pp. 97-102.

The reactions of copepods to various stimuli and the bearing of this on daily depth migrations, by G. H. Parker. Bulletin for 1901, pp. 103–123.

The gas in the swim-bladder of fishes. Biliary calculi in the squeteague, by R. W. Tower. Bulletin for 1901, pp. 126–135, plate 21. Description of new species of shad (*Alosa ohiensis*), with notes on other food-fishes

of the Ohio River, by Barton Warren Evermann. Report for 1901, pp. 273-288.

There have been distributed during the year 1,815 bound and 19,210 pamphlet publications of the Commission.

The Museum of Comparative Zoology, Cambridge, Mass., has published under the general title, "Reports on the scientific results of the expedition to the tropical Pacific, in charge of Alexander Agassiz, by the U.S. Fish Commission steamer Albatross, from August, 1899, to March, 1900, Commander Jefferson F. Moser, U. S. N., commanding":

- I. Preliminary report and list of stations, by Alexander Agassiz; with remarks on deep-sea deposits, by Sir John Murray. (Vol. xxvi, No. 1.) II. Some species of Partula from Tahiti: A study in variation; by Alfred Golds-
- borough Mayer. (Vol. xxvi, No. 2.)
- III. Meduse, by Alexander Agassiz and Alfred Goldsborough Mayer. (Vol. xxvi, No. 3.)

APPROPRIATIONS.

The appropriations available for conducting the Commission during the fiscal year 1902 were as follows:

| Salaries | \$234, 120 |
|--|------------|
| Miscellaneous expenses: | |
| Administration | 12,500 |
| Propagation of food-fishes. | 175,000 |
| Inquiry respecting food-fishes | 22,500 |
| Statistical inquiry | 7,500 |
| Maintenance of vessels. | 35,000 |
| For improvement and enlargement of stations at— | , |
| Green Lake, Me. | 4,000 |
| Woods Hole, Mass | 2,000 |
| For purchase of additional land and improvements at- | , |
| San Marcos, Tex. | 8,000 |
| Neosho, Mo | 7,500 |
| For the construction of a steamboat for use on the Mississippi River | 5,000 |
| For the establishment of a lobster hatchery on the coast of Maine | 10,000 |
| For the establishment of a fish-cultural station at Tupelo, Miss | 20,000 |
| | |

A report of the expenditure of these appropriations will be made to Congress in accordance with law.

GEORGE M. BOWERS.

Commissioner.

21

REPORT ON THE PROPAGATION AND DISTRIBUTION OF FOOD-FISHES.

By JOHN W. TITCOMB, Assistant in Charge.

PROPAGATION OF FOOD-FISHES.

The work of the division was under the direction of Mr. W. de C. Ravenel until February 15, 1902, when he resigned to accept the position of administrative assistant in the National Museum. The vacancy was filled by the promotion of Mr. John W. Titcomb from the superintendency of the St. Johnsbury, Vt., Station.

In addition to the usual work of the division, which consists of the general direction of fish-cultural work, including the propagation and distribution of fish from the various stations, Mr. Ravenel was representative of the Commission at the Pan-American Exposition and also at the Charleston Exposition, and continued the duties of representative after assuming his new position in the National Museum.

There has been no change in the policy of the Commission in respect to the division of fish-culture, and the work is conducted on the same general lines as in the past, the results exceeding those of any previous vear. The total number of fish and eggs distributed was 1,495,543,374, or an increase of 321,709,912 over the output of the preceding year. Of these 1,480,642,960 were for the development of the commercial fisheries of the country, and 14,900,414 may be regarded as strictly game fishes. The number of applications received during the year was 3,814, an increase of 762 over the previous year, or 25 per cent. This is in addition to the large number of fishes distributed and planted by the Commission from the various stations, principally commercial fishes. This increase in the output of the stations is attributable to several causes, largely to the increased appropriation provided for by Congress and also to the fact that the general conditions for collecting eggs at most of the stations were unusually favorable during the spawning seasons. The results reflect great credit upon the esprit de corps of the superintendents and other employees in the field.

The following is a list, in systematic order, of the fishes propagated and distributed by the Commission, with the scientific name and the common name or names. The fishes artificially propagated are designated *; those simply collected and distributed are indicated thus \$; the introduced species are shown by \$\$; and the species propagated as food for other fishes are represented by an exclamation mark. List of fishes propagated and distributed by the Fish Commission.

Siluridæ, THE CAT-FISHES.

- * § Ictalurus punctatus (Rafinesque). Spotted Cat; Blue Cat; Channel Cat.
- * § Ameiurus nebulosus (Le Sueur). Horned Pout; Bullhead; Yellow Cat.
- Catostomidæ, The Suckers and Buffalo-fishes.

§ Ictiobus bubalus (Rafinesque). Small-mouthed Buffalo-fish.

Cyprinidæ, THE MINNOWS AND CARPS.

!§§ Cyprinus carpio Linnaeus. Carp. (Cultivated varieties, German Carp, Leather Carp, Mirror Carp, etc.)

Clupeidæ, THE SHADS AND HERRINGS.

* Alosa sapidissima (Wilson). Shad.

Salmonidæ, The Salmons, TROUTS, WHITE-FISHES, ETC.

- * Coregonus clupeiformis (Mitchill). White-fish.
- * Argyrosomus artedi (Le Sueur). Lake Herring; Cisco.
- * Oncorhynchus tschavylscha (Walbaum). Quinnat Salmon; Chinook Salmon; Tyee Salmon; King Salmon.
- * Oncorhynchus kisutch (Walbaum). Silver Salmon; Coho.
- * Oncorhynchus nerka (Walbaum). Blueback Salmon; Red-fish; Sockeye.
- * Salmo gairdneri Richardson. Steelhead; Hardhead; Salmon Trout.
- * Salmo salar Linnæus. Atlantic Salmon.
- * Salmo sebago Girard. Landlocked Salmon.
- * Salmo lewisi Girard. Yellowstone Lake Trout; Cut-throat Trout; Black-spotted Trout.
- * Salmo pleuriticus Cope. Colorado River Trout; Black-spotted Trout.
- * Salmo macdonaldi Jordan & Evermann. Yellow-finned Trout.
- * §§ Salmo trutta Linnæus. Sea Trout; Salmon Trout.
- * §§ Salmo trutta levenensis (Walker). Loch Leven Trout.
- * §§ Salmo fario Linnæus. European Brown Trout; Von Behr Trout.
- * Cristivomer namaycush (Walbaum). Lake Trout; Mackinaw Trout; Longe; Togue.
- * Salvelinus fontinalis (Mitchill). Brook Trout; Speckled Trout.
- * Salvelinus agassizii (Garman). Dublin Pond Trout.
- * Salvelinus aureolus Bean. Golden Trout; Sunapee Lake Trout.

Thymallidæ, THE GRAYLINGS.

* Thymallus montanus Milner. Montana Grayling.

Esocidæ, THE PIKES.

- § Esox lucius Linnæus. Common Pike; Pickerel.
- § Esox vermiculatus Le Sueur. Little Pickerel; Grass Pike.
- Centrarchidæ, The Basses, Sun-fishes, and Crappies.
 - * § Pomoxis annularis Rafinesque. Crappie.
 - * § Pomoxis sparoides (Lacépède). Strawberry Bass; Calico Bass.
 - * § Ambloplites rupestris (Rafinesque). Rock Bass; Red-eye; Goggle-eye.
 - * § Chænobryttus gulosus (Cuvier & Valenciennes). Warmouth; Goggle-eye.
 - § Micropterus dolomieu Lacépède. Small-mouthed Black Bass.
 - * § Micropterus salmoides (Lacépède). Large-mouthed Black Bass; Straw Bass.
 - * § Lepomis pallidus (Mitchill). Bluegill.

Percidæ, THE PERCHES.

- * § Stizostedion vitreum (Mitchill). Pike Perch; Wall-eyed Pike; Yellow Pike; Blue Pike.
- * § Perca flavescens (Mitchill). Yellow Perch.

Gadidæ, THE CODS.

* Gadus callarias Linnæus. Cod.

Pleuronectidæ, THE FLOUNDERS.

* Pseudopleuronectes americanus (Walbaum). Winter Flounder.

23

INSPECTIONS.

During the month of November Mr. Ravenel visited Detroit and Northville to confer with the superintendent of the Northville Station and the State fish and game warden of Michigan, and to arrange for the collection of lake-trout eggs in the Michigan waters of the Great Lakes. He also visited Put-in Bay Station, inspected the improvements recently made, and found the station in very good condition. Various recommendations were made for further improvements—first, for the dredging out of the channel and a place for anchoring the penning erates. The station very much needs a residence for the superintendent. The only available house is over 2 miles from the hatchery.

In order to familiarize himself with the work of the various stations over which he had recently assumed charge, Mr. Titcomb began a series of inspections in March, and before the close of the year had visited the following stations in the order named:

 Wytheville, Va., Station.
 Gloucester, Mass., Station.

 Erwin, Tenn., Station.
 Swanton, Vt., Substation.

 Bullochville, Ga., Station.
 Nashua, N. H., Station.

 Sean Marcos, Tex., Station.
 Battery Station, Havre de Grace, Md.

 Syna Point, Md., Station.
 Steamer Fish Hawk, Delaware River.

 Bedenton, N. C., Station.
 St. Johnsbury, Vt., Station.

All of these stations were found to be in good condition, but each one seemed to have more or less need for improvement in order to keep the work up to its fullest capacity. At the Wytheville Station the buildings and ponds were found to be in very good repair. An ice-house is needed, as it is possible to collect at the station all the ice necessary for fish-cultural work if storage room is provided for it. The superintendent was instructed to introduce a power chopper for preparing fish food. A bad feature about this station is the fact that the spring is gradually failing in the amount of water flowing from it.

The Erwin Station is very attractive in appearance, and everything being new was in good repair with a few exceptions. The superintendent's residence is small and cheaply constructed; it should be enlarged and the chimney rebuilt. Arrangements were made for the construction of five new ponds for the propagation of bass and other pond fishes and for inclosing the station with a hog-proof wire fence.

The station at Bullochville, Ga., was found to be in first-class condition, both as to buildings and ponds. One of the main sources of water supply is not on the station property. It would be a great improvement to the station if an additional purchase of land could be made, to include the source of water supply and straighten the boundary lines.

At Neosho the buildings had been recently repaired under a special appropriation and the ponds were in course of construction and repair. The station is very inadequately supplied with water, and an additional supply can be obtained only at large expense.

The station at San Marcos, Tex., and everything connected with its conduct, was very satisfactory. The demands upon this station are increasing annually, owing to the opening up of new territory and the remarkable results attained from the fishes already distributed. These conditions make it desirable to acquire additional hand for pond culture.

The shad stations at Bryan Point and Havre de Grace, Md., were visited during the period of active operations, and everything was found to be working most satisfactorily. The *Fish Hawk*, engaged in shad work on the Delaware River, was also visited before the close of the egg-collecting season.

The shad station at Edenton has in connection with it three marsh ponds for the propagation of black bass and crappie, but it is questionable whether the station will ever be of value for other work than the propagation of shad. It is a well-built and well-equipped station, in fact, the most complete shad station of the Commission. It would be economy, however, to have in connection with it a boathouse to shelter the launches and other boats and to give additional storage room.

When the station at Gloucester, Mass., was visited everything was in readiness for the lobster work. Arrangements were made for the construction of a breakwater in which to keep the fish-cars for retaining live cod and lobsters. The capacity of the station for fish-cultural work should be increased by an addition to the hatchery.

At Swanton the work of collecting pike-perch eggs on Missisquoi River was placed in charge of Supt. Livingston Stone, of Cape Vincent Station, and arrangements made for its conduct during the season.

At the Nashua Station the chief problem was the shortage of the water supply during the summer season, and methods for increasing the supply were fully discussed with the superintendent. In the hatchery there had been an unusual mortality among the brook-trout fry, undoubtedly due to the lack of sufficient flow of water upon the eggs during the period of incubation.

At the time the Cape Vincent Station was visited no fish-cultural work was going on, the product of the station having been previously distributed. This station is entirely dependent upon the collections of eggs from other stations for its source of supply. The capacious hatchery building is capable of turning out a great many young fish and is well supplied with the necessary apparatus and equipment. Arrangements were made for obtaining water from the city works upon a more economical basis. The heating apparatus at this station is not satisfactory, owing to the inordinate amount of coal consumed by it. A new and more economical heating plant should be installed. Extensive repairs upon the wharf will soon be necessary.

The St. Johnsbury Station is still inadequately supplied with water, the special appropriation for necessary improvements being kept unimpaired until satisfactory arrangements can be made for its economical expenditure.

The traveling expenses incurred were much less than the saving at one station, resulting from the changes made as a result of the inspection.

METHODS OF FISH-CULTURE.

Few improvements in the methods of fish-culture can be recorded for the year. The most notable one may be the method of taking salmon eggs at the Baird, Cal., Station and substations, whereby from 10 to 15 per cent more eggs are obtainable from the same number of fish than heretofore. This is accomplished by cutting the salmon open after the usual stripping and washing the bloody eggs thus obtained in a normal salt solution before fertilizing them, as explained in detail under the summarized report of Baird Station. This improved method will be adopted at the other salmon stations the coming year.

At Put-in Bay, Ohio, Superintendent Downing has devised a new hatching-jar along the same general lines as the Stranahan jar, except that it is of a different shape and of greater capacity. It has been adopted for Put-in Bay Station.

In pond culture, by which is meant the propagation of the basses and other fishes, the eggs of which are handled and hatched in ponds by the natural process, little definite progress has been made. The general feeling among fish-culturists in charge of pond stations is that the ponds for the propagation of bass and other fish should be made much larger than at present—in fact, as large as possible and still have them entirely under control so that the fish can be removed as wanted.

The following stations and auxiliary stations were operated during the year, and the work at each is reviewed in detail in the abstracts of the reports from the various superintendents:

| Green Lake, Maine. | Detroit, Michigan. |
|-------------------------------------|--|
| Craig Brook, Maine. | Alpena, Michigan. |
| Grand Lake Stream, Maine. | Sault Ste. Marie, Michigan. |
| St. Johnsbury, Vermont. | Duluth, Minnesota. |
| Nashua, New Hampshire. | Quincy, Illinois. |
| Woods Hole, Massachusetts. | Manchester, Iowa. |
| Gloucester, Massachusetts. | Bellevue, Iowa. |
| Cape Vincent, New York. | San Marcos, Texas. |
| Swanton, Vermont. | Neosho, Missouri. |
| Steamer Fish Hawk (Delaware River). | Leadville, Colorado. |
| Battery Station, Maryland. | Spearfish, South Dakota. |
| Bryan Point, Maryland. | Bozeman, Montana. |
| Fish Lakes, Washington, D. C. | Baird, California. |
| Central Station, Washington, D. C. | Battle Creek, California. |
| Wytheville, Virginia. | Mill Creek, Ćalifornia. |
| Edenton, North Carolina. | Rogue River, Oregon. |
| Erwin, Tennessee. | Clackamas, Oregon. |
| Cold Springs, Georgia. | Little White Salmon River, Washington. |
| Put-in Bay, Ohio. | Baker Lake, Washington. |
| Northville, Michigan. | |

GREEN LAKE STATION, MAINE (E. E. RACE, SUPERINTENDENT).

The work at the Green Lake Station has been confined entirely to the propagation of the brook trout and landlocked salmon. During the summer months, in addition to the usual fish-cultural work, investigations were made with the view to establishing new field stations for the collection of eggs, and as a result operations were inaugurated at Alligator Lake, in Hancock County, and Sourdnahunk Lake, in Piscataquis County. The field stations operated in previous years at Green Lake, Pattens Pond, and Branch Pond were also reopened and operated.

At Alligator Lake a log camp was constructed for the shelter of the fishermen, and a temporary hatchery for eying eggs was erected and equipped with the necessary apparatus for conducting operations. At this point it was thought that brook trout could be captured on the bars and landlocked salmon at the outlet of the lake, but although the water and weather were both favorable, and the station in the hands of experienced fishermen, no salmon and only 52 brook trout were captured. From the trout 21,000 eggs were obtained, 7,000 of them being transported direct to Green Lake Station within 24 hours after being taken from the fish. The remaining 14,000 were laid down in the temporary hatchery to be eyed, but after holding them from 15 to 20 days in a temperature of 38° F., it was found that the expense of developing them at the point of collection would be very large; they were therefore transferred to Green Lake Station before the eye-spots appeared, but all died en route.

Sourdnahunk Lake is 55 miles northwest of Patten, in an unbroken wilderness, and is probably at the highest elevation of any lake of equal size in the State. It is 4 miles long by 14 miles wide, and is the breeding-ground for nearly the entire west branch of the Penobscot River. No fish are found in the lake except brook trout and shiners. The adult trout averaged a trifle less than a pound in weight, the largest weighing 2 pounds. Owing to the expense of transporting suitable material from Patten, nets were used for the leads of the traps and sides of the confining pens, but these were destroyed by a moose swimming around in the lake about the time the fishing season began. Temporary pens were built of poles and the fish were captured by means of seines. All the fish that could be safely held in these pens were caught before any of them had commenced working on the spawning-grounds, as many as 800 being taken at one haul of the seine. The total number recorded as captured was 4,275 males and 5,725 females; 4,047 females were stripped and yielded 1,470,000 eggs. As the lake froze over two weeks earlier than was expected, the rest of the females were liberated by cutting holes through the ice and removing the stakes in the pens. The eggs were eyed in troughs set up in a small tent, the troughs being not more than 6 inches above the ground: but notwithstanding the fact that two fires were kept night and day, the water temperature dropped to the freezing-point several times, and 190,000 were lost by freezing to the bottoms of the hatchingtroughs. On February 19 the eggs were packed out, but on account of the deep snow between Sourdnahunk Lake and Patten they were on the road three days, and 10.250 died en route. Of the 1.280,000 which reached Patten in good condition, 320,000 were shipped to the Maine Fish Commission and 50,000 to the Parmachenee Club, Camp

27

Caribou, Maine. The others were transferred to Green Lake to be hatched, and the losses on the eggs and fry were very small.

Operations at Green Lake for collecting landlocked-salmon and brook-trout eggs were inaugurated as in previous years, but owing to the fact that the water in the lake was 14 inches lower than during any fishing season in the past seven years no fish were captured in the trap at Great Brook near the spawning-house, it being impossible for them to get over the bars at the mouth of the brook. This is the first season since the establishment of the hatchery that the fish were unable to ascend Great Brook during the spawning season. A large pound net was operated on what is known as the middle ground. between the hatchery wharf and the outlet of the lake, but owing to unprecedentedly low water no fish were captured in it. A pound net set southeast of the bar at Great Brook in 10 feet of water captured 2 brook trout and 164 salmon, half of each species being females. From these fish 2,000 trout and 194,000 salmon eggs were taken. The female salmon caught late in the season were all small, and averaged a trifle over 2,365 eggs to the fish. Some eggs were from immature salmon, apparently 4 or 5 years old, and, as a result, 25,000 died within a few days after being laid down in the troughs.

At Patten Pond, owing to the low water, only 56 brook trout and 2 male salmon were captured. The trout yielded 35,000 eggs, which were transferred to Green Lake Station in good condition.

In September the collecting station at Branch Pond (Winkempaugh Brook) was repaired and put in shape for the season's work. The water at this point was higher and general conditions more favorable for the capture of fish than at any of the other field stations. However, the lake froze over ten days earlier than the previous year, which prevented the capture of the usual number of salmon. On October 14 the only rain of any importance during the fishing season raised the water in the brook from 8 to 10 inches, and as a result 110 brook trout (25 males and 85 females) and 35 salmon (22 males and 13 females) were captured. The total take of fish at this point for the season was 142 trout and 50 salmon. Owing to the scarcity of male brook trout, 16 were captured at Harriman's Pond and transferred to this station. but after using all the male fish available there were still 25 large females unstripped, and as it was impossible to obtain milt for fertilizing their eggs, they were liberated. The total collections at Branch Pond amounted to 56,000 salmon eggs and 85,000 brook-trout eggs.

The landlocked-salmon eggs secured at all points numbered 250,000, and 45,000 of these were shipped to applicants in Massachusetts, Vermont, New York, Utah, and Colorado. The remainder were hatched for rearing and distribution as yearlings in the fall. The stock set aside for this purpose was materially increased during the spring by the transfer of 100,000 young salmon from the Craig Brook Station, the loss on these in transit between the stations amounting to 1,551. In addition to the 1,613,000 brook-trout eggs collected at the field stations, 200,000 were purchased from George F. Lane, Silver Lake, Mass. These reached the station in excellent condition, only 1,370 having died en route, and the resulting fry were strong and active, the total losses on eggs and fry not exceeding 4 per cent. All but 15,000 of this stock, which are being held for brood fish, were distributed in May and June with the fry derived from the collecting stations, the total output aggregating 1,081,388. This work was all done by the regular employees of the station, and was completed by June 20.

The following shows the field stations operated in connection with Green Lake Station, and the number of fish and eggs obtained at each:

| Stations. | Species. | Males. | Females. | Total. | Number of eggs. |
|------------|--|--------------------------|---|---|---|
| Green Lake | Landlocked salmon Brook trout do Landlocked salmon. | $29 \\ 4,275 \\ 20 \\ 1$ | 101 22 27 5,725 32 1 82 | $ \begin{array}{r} 142 \\ 50 \\ 56 \\ 2 \\ 10,000 \\ 52 \\ 2 \\ 164 \\ 16 \end{array} $ | $\begin{array}{r} 85,000\\ 56,000\\ 35,000\\ \hline 1,470,000\\ 21,000\\ 2,000\\ 194,000\\ \end{array}$ |
| Total | | 4, 494 | 5,990 | 10,484 | 1,863,000 |

At the close of the year the stock of fish on hand consisted of 264,088 landlocked salmon fry and 129,514 brook-trout fry.

A special appropriation for general repairs and improvements having been provided, the western wing of the dam at Rocky Pond, 53 feet long, was removed and replaced by a new wing 189 feet long, and surmounted with 4-foot flush boards. Two hundred and fifty feet of the main supply flume was replaced and 5,000 feet of it repaired. For the purpose of housing the steamer Senator and other boats during the winter, a boat-house 57 feet long by 22 feet wide, with a roller railway 384 feet long leading to it, was constructed near the station wharf. The hull of the steamer Senator was replanked, calked, and otherwise Sixteen hatching-troughs were constructed for increasing repaired. propagation facilities in the hatchery; the bridges between the hatchery and Rocky Pond were repaired, and much work was done in grading around the north and south reservoirs, hatchery buildings, and rearingponds. The coal shed at the outlet of Green Lake, together with 7 or 8 tons of soft coal, was burned on October 17, it presumably having been struck by lightning.

CRAIG BROOK STATION, MAINE (C. G. ATKINS, SUPERINTENDENT).

The work at the Craig Brook Station and its two auxiliaries, Mattagamon and Grand Lake Stream, has been applied to the propagation of the Atlantic salmon, landlocked salmon, quinnat salmon, steelhead trout, brook trout, rainbow trout, Scotch sea trout, and grayling.

The work at the Mattagamon auxiliary was wholly tentative, aiming at the capture of wild Atlantic salmon near their natural spawningbeds for the collection of spawn, as a substitute for the present system of obtaining spawn from salmon purchased from fishermen about the mouth of the river and impounded during the summer in a stream near Craig Brook. At the beginning of the year a weir of novel form was in operation and an inclosure ready to capture all salmon seeking to ascend the East Branch, but on account of the very low water the salmon failed almost wholly to surmount the dams in its lower course, and scarcely any reached the East Branch. In consequence of their failure the station was abandoned in August.

At the beginning of the year the stock of Atlantic salmon consisted of 238 adults in the Dead Brook inclosure, 300,295 fry, and 411 fish 2 years old. Of the 2-year-old fish 16 were distributed in August, and the remainder were carried through the year with a loss of 19. The fry were reared to fingerlings, and as a result 282,400 were distributed in October and 351 kept to the end of the year. From the 238 adult salmon 832,300 eggs were obtained, of which 315,000 were distributed in the winter and 397,499 hatched in March and April. Of the fry thus obtained 48,715 were liberated in June, and 326,186 remained on hand at the close of the year in course of rearing. Preparations have been made for enlarging the Atlantic salmon operations the coming year by the collection in May and June of 614 adult salmon, of which 589 remained alive at the close of the year.

The stock of landlocked salmon on hand at the opening of the year consisted of 4 broods, of which 24,229 were fry and 1.796 were from 1 to 3 years old. The fry were all fed until November, when 20.758 of them were distributed. Of the balance 2.407 remained on hand at the end of the year. At the Grand Lake Stream auxiliary 72,312 landlocked-salmon fry were on hand at the beginning of the year. These were a part of those reserved for the preservation of the species in the waters where the eggs were collected, and 53,825 were reared and liberated in Grand Lake Stream and vicinity in October. During October and November the run of wild salmon from Grand Lake down into the stream for spawning purposes was unusually heavy, and the weir intercepted 3,210, of which 1,464 were males and 1,746 females. The eggs obtained from the latter amounted to 1,448,274, the largest number collected at this point since 1884. Of these, 225,000 eggs were distributed, and there were hatched from those retained at Grand Lake Stream 505,513 fry and at Craig Brook 282,482. Of the fry at Grand Lake Stream 429,785 were liberated in the lake and stream in June and the remainder, 68,949, were held for feeding. From Craig Brook 100,000 of the fry were transferred to the Green Lake Station in May, 90,000 were distributed in June, and on June 30 there were 67.546 on hand.

Of the 2,137 fingerling brook trout on hand at the beginning of the year 1,243 ware distributed as yearlings. From the few adult brook trout on hand 8,500 eggs were collected, and the fry from these eggs, amounting to 5,475, were distributed in local waters.

Forty-one quinnat salmon hatched in 1897 are kept in a deep pond for experimental purposes.

Of steelhead trout several old broods have been kept for experiment, and two of the broods, numbering 1,019, are still retained. One brood afforded 8,500 eggs. From these and from a lot received from Rogue River there were hatched 33,994 fry. These suffered from an obscure disease, and only 12,046 were left for distribution.

In October there were distributed 3,350 rainbow trout hatched in 1901 and 1,056 hatched in 1900, leaving only a lot of 33 fish hatched in 1899.

The Scotch sea trout, like other species, has deteriorated under domestication, the vitality of the eggs and fry growing constantly less. In October 6,937 yearlings were distributed, and in November 68,950 eggs were taken from the brood stock. Of these 10,000 were distributed in the egg stage; the remainder were hatched, and as a result 7,694 fry were distributed in June. The adult stock on hand is 459. The results from the introduction of this species are not encouraging, and their propagation will be discontinued.

From 100,000 grayling eggs shipped from Montana in May, 86,615 fry were hatched, and 36,333 fry were distributed in local waters. An attempt was made to feed the balance, but about June 3 a sudden and heavy mortality attacked them, and by the end of the month only 1,775 remained. This remnant has, as observed at other stations, grown very rapidly.

The fish food consisted of hogs plucks, purchased at an abattoir near Boston. The total consumption was 5,346 plucks, weighing 23,790 pounds and costing \$310.04, including transportation.

From the entire stock of fry of all species in the spring of 1901 84.4 per cent were reared to fingerlings and distributed in October and November. The Atlantic salmon did a trifle better than this, and the landlocked salmon best of all, 94.4 per cent having been reared to the fingerling stage. The aggregate production of the station for the year, including auxiliary stations, is as follows: Eggs collected, 2,516,524; eggs distributed, 550,000; fish hatched, 1,321,490; fish distributed, 1,099,929.

aAt Craig Brook.

bAt Grand Lake Stream.

ST. JOHNSBURY STATION, VERMONT.

Mr. John W. Titcomb, the superintendent of this station, having been appointed in charge of the Division of Fish-culture of the U. S. Fish Commission, at Washington, D. C., he was succeeded on February 15 by Mr. E. N. Carter.

During the summer preparations were made for the collection of brook-trout eggs in the waters controlled by the Laurentian Club in Canada, in Lake Mitchell at Sharon, Vt.; Darlings Pond, Groton, Vt., and Noyes Lake, Chittenden, Vt. At Darlings Pond, where the run of fish has heretofore been very large, the opposite conditions prevailed. The collecting season was unusually dry throughout New England and also in the Province of Quebec, where, in the Laurentian Mountains, the lumbermen reported the water in the streams as lower than it had been since 1847. Owing to the excessive drought the trout did not run as early as usual, and in many instances the eggs were inferior in quality. In the Province of Quebec 6,000 trout were handled in one stream, but the ovaries of the females seemed diseased and the few eggs secured were of inferior quality. In the Laurentian Mountains most of the fish spawned around the shores of the lakes late in the season after the ice had formed on the surface, and there were very few places where the fish ascended the streams to spawn.

At Lake Mitchell the first eggs were secured October 9 and the last on November 16. Of the 324,129 collected, 150,300 were shipped on assignments and the remaining 173,829 were transferred to the St. Johnsbury Station to be hatched.

At Darlings Pond the spawning season extended from September 30 to November 11, and resulted in the collection of 156,000 eggs, 15,000 of which were shipped on assignments. The remainder were hatched at St. Johnsbury.

From Noyes Lake 53,980 eyed eggs were secured, and after shipping 25,000 to fill assignments, the remaining 28,930 were transferred to St. Johnsbury and hatched, producing 22,661 fry. The work at this point began late in the season—October 18—and lasted only five days.

In addition to the eggs secured at the different field stations 250,000 domesticated-trout eggs were purchased of commercial fish-culturists; a consignment of 40,000 was received from Carolina, R. I., in exchange for 35,000 wild-trout eggs, and 39,500 were obtained by the same method from East Freetown, Mass. An assignment of 8,000 domesticated-trout eggs was donated by Mr. L. B. Handy, of South Warcham, Mass., to be used for experimental purposes. All of these eggs were hatched at the St. Johnsbury Station, and the fry were distributed with those derived from the field station in May and June, only 5,802 being retained for rearing.

While the results from the domesticated-trout eggs do not compare favorably with those from the eggs of the wild brook trout, very good results obtain by stipulating that the domesticated eggs must be the product of fish at least $2\frac{1}{2}$ years old.

The rainbow trout on hand began spawning early in April and eggs were obtained from them at intervals to the end of the month. Only 17,845 were secured, and these were very inferior in quality. The fry were retained for rearing. The propagation of the rainbow trout at the St. Johnsbury Station has never been very successful, owing to the extremely cold water. A shipment of 50,000 eggs was also received from the Manchester Station, but they proved to be very poor and only a few fry were hatched from them.

During the winter and spring 200,000 lake-trout eggs were received from Duluth, Minn; 25,000 landlocked-salmon eggs from East Orland, Me.; 50,000 grayling eggs from Bozeman, Mont., and 50,000 steelhead-trout eggs from the station at Rogue River, Oregon. These hatched with good results, and all of the fry were distributed, with the exception of the landlocked salmon and a few of the grayling, which were retained for rearing.

The results of the fish-cultural work at St. Johnsbury for the past five years have proved extremely satisfactory, as demonstrated by the large catches of lake trout from Big Averill Pond, Averill, Vt., which never contained any of that species until they were introduced by the Commission in 1897. From Little Averill Pond, Averill, Vt., in which salmon never existed until introduced from the St. Johnsbury Station, large quantities of salmon have been taken. From Caspian Lake, at Greensboro, Vt., it is estimated that 6 tons of fish were taken with hook and line between May 1 and September 1, 1901, and a proportionate amount for the months of May and June, 1902. Ever since the establishment of the St. Johnsbury Station this lake has been annually stocked with lake trout, landlocked salmon, and brook trout. The species mostly caught are the lake trout and landlocked salmon, speckled trout not having produced very satisfactory results. The introduction of the steelhead trout in Vermont waters has also been verv successful.

The introduction of the lake trout in Big Averill Pond afforded an opportunity of ascertaining the actual growth of the fish from the fry stage. The plant of 1897 afforded good fishing for anglers during the season of 1901, the largest fish taken that year weighing $3\frac{3}{4}$ pounds. The next in size weighed $2\frac{3}{4}$ pounds, the next $1\frac{1}{2}$ pounds, and the smallest specimens ranged from 9 to 10 inches in length. Many fish of the sizes mentioned were taken, and there was very little variation from the weights given above, indicating that the fry planted in 1897 had attained in 1901 a weight of $3\frac{3}{4}$ pounds, and that the other sizes were the results of plants in the succeeding years, those from 9 to 10 inches long being a year and a half old from the time the eggs were taken.

33

34 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

During May and June, 1902, the anglers reported an average of about 200 pounds a day from this lake, and the largest fish, which undoubtedly resulted from the plant in 1897, weighed $5\frac{1}{2}$ pounds.

The stock on hand at the close of the year is shown by the following table:

| 1 | Calendar year in which fish were hatched. | | | | | | | |
|-----------------|---|-------|-------|-------|-------|--------------------|--|--|
| Species. | 1902. | 1901. | 1900. | 1899. | 1898. | 1897 or before. | | |
| Steelhead trout | $20,500 \\ 5,734$ | | | | | | | |
| Grayling | $1,000 \\ 5,802 \\ 17,786$ | | | 14 | | | | |
| Total | 50, 822 | | | 14 | -1 | 90 | | |

NASHUA STATION, NEW HAMPSHIRE (W. F. HUBBARD, SUPERINTENDENT).

Besides the brood stock of fish on hand at the beginning of the year, there were 63,810 brook-trout fry which were reared to yearlings before being distributed, the product of the same amounting to 62,500 yearlings. There were also on hand at this time 46,100 landlockedsalmon fry hatched from eggs belonging to the New Hampshire Fish Commission on shares. The product of these fish amounted to 22,400 yearlings, one-half of which were turned over to the New Hampshire Commission and the balance distributed in the usual manner.

During the summer a disease known as pop-eye attacked the 55 adult rainbow trout retained as a brood stock. The eyes protruded from the head, and little bubbles, some of them as large as peas, appeared on the gill-covers, fins, and other parts of the body. When the disease made its appearance the fish were being held in one of the rearing-ponds 100 by 8 feet in dimensions and with plank sides and bottom. In order to cure the affection, the fish were transferred to a larger pond, 150 by 100 feet in area, with natural earth embankments, and as a consequence only two of them died. When removed from this pond, in November, they were found to be in good condition and produced eggs during the following spawning season.

In the course of the summer the superintendent visited various places in the State with the view to finding suitable locations for field stations, and as a result a station for the collection of brook-trout eggs was, in September, established at the Balsams, 12 miles east of Colebrook, the nearest railroad station. Another station was established at Lake Sunapee for the collection of eggs of the brook trout, golden trout, and landlocked salmon.

At the Balsams the fish were caught by means of a trap, in a brook tributary to the pond, and held in pens. The eggs were transferred daily by wagon 12 miles to the State hatchery at Colebrook, where they were eved, and in December shipped to the Nashua Station. At Lake Sunapee the brook trout were captured in traps and also, along with the landlocked salmon and golden trout, in fine-meshed gill nets. The eggs at Lake Sunapee were placed in hatching-troughs at the lake, where they were kept for four or five days, or until enough had been collected to warrant making a shipment, when they were placed in 2-quart glass preserve jars, filled three-fourths full of eggs and brimful of water. The jars were then sealed and packed in a box with hay and ice, and in this condition were shipped to Nashua. The eggs were about eight hours in the jars in transit and the jars were not opened during that period, but all eggs shipped in this manner were received at Nashua in good condition and with very small loss.

The brook trout at the station began spawning October 24 and continued until the middle of January, when 1,959 females, nearly all of which were $2\frac{1}{2}$ years old, had been stripped and 1,009,470 eggs secured, or an average of about 512 per fish. The eggs began hatching early in February, the period of incubation being 104 days.

There was an unusual mortality among the brook-trout fry about the time they began to feed, and the cause of this mortality is attributed to the fact that the station was inadequately supplied with water during the early stages of incubation. In order to determine whether the same mortality would occur among fry hatched under favorable conditions, but reared at the Nashua Station, 100,000 brook-trout fry were transferred from the St. Johnsbury Station to Nashua and were successfully reared.

The following table shows the number of eggs and fry received at the station during the year:

| Species. | Source of supply. | Eggs. | Fry. |
|---|---|-------------------|------|
| Brook trout. | Taken at Lake Sunapee | 70, 500 | |
| Do Golden trout Landlocked salmon | Taken at the Balsams Taken at Lake Sunapeedo | 123,800 23,000 | |
| Do Rainbow trout Lake trout. | | 25,500 | |
| Brook trout Total | | | |

The distributions of fish from the station were all made by the regular station force, and the following table shows the number of fish and eggs shipped from the station during the year:

| Species. | Eggs. | Fry. | Yearlings. | Two years or over. |
|---|---------|----------------------------|----------------|-----------------------|
| Brook trout | | 470,000 70,000 8,000 | $62,500 \\ 15$ | 294 |
| Lake trout . Landlocked salmon Grayling | | 160,000 | 11,200 | 74 |
| Total | 100,000 | 708,000 | 73, 715 | 376 |

The stock of fish on hand at the close of the year is shown by the following table:

| | Calendar year in which fish were hatched. | | | | | | |
|-------------------------------|---|-------|--------|-------|-------|--|--|
| Species. | 1902. | 1901. | 1900. | 1899. | 1898. | | |

| Total | 190, 978 | 754 | 4, 464 | 5 | 136 | | |

Woods Hole Station, Mass. (E. F. Locke, Superintendent).

The collection of brood cod off Nantucket Shoals was commenced by the schooner *Grampus* on October 2 and closed on November 3, when 3,179 had been captured and conveyed alive to Woods Hole Station. These fish varied in weight from 3 to 10 pounds, the average being between 6 and 7 pounds, and from them 118,745,000 eggs were taken, which were all of good quality, with the exception of a few of the last lots secured. Of the brood fish 2,106 were released alive, the remainder dying from natural causes. Some of the smaller fish were barren and yielded no eggs.

On November 29 the *Phalarope* reached Plymouth, Mass., and the auxiliary station at that point was opened on December 2. The first eggs were taken on December 3, and collections were obtained up to February 28, when 125,559,000 had been secured. Of these 38,621,000 were shipped to the Gloucester Station and the remainder, 86,938,000, to Woods Hole.

The total number of cod eggs received at Woods Hole amounted to 205,683,000, from which 128,810,000 fry were hatched and planted.

During the month of January arrangements were made for the collection of flat-fish eggs, and on February 5 the boats, nets, and other equipment were sent to Waquoit Bay, but owing to the ice in the bay it was impossible to set the nets until February 15, and it was only done then by breaking up quantities of ice. Nets were also set in the harbor near the station, and from these two fields 553 females were secured, of which 105 died and 123 failed to deposit eggs. The product of the egg-bearing fish amounted to 194,059,000 eggs, of which 144,800,000 were secured from the fish taken at Waquoit Bay. The average yield of eggs this season was larger than that of last year, the average from the fish captured at Woods Hole being 808,000 per fish and from those taken at Waquoit Bay 548,000 per fish.

About the middle of April arrangements were made for collecting egg-bearing lobsters at Scituate, Mass., and from the fishermen at Buzzards Bay and Vineyard Sound. At Plymouth only a few men were fishing and this territory was abandoned. Later in the season a

REPORT OF COMMISSIONER OF FISH AND FISHERIES.

man was employed at Noank, Conn., to collect egg-bearing lobsters from the fishermen there and at Stonington. The work heretofore done at Newport was discontinued because the commissioners of inland fisheries for the State of Rhode Island were engaged in collecting at that point, and arrangements were made to receive such eggs as the State commission did not have use for. The receipts from these sources were less than one-fourth of the number received last year. but the receipts from Buzzards Bay and Vineyard Sound showed a slight increase over the collections of the previous year, and the collections from Connecticut waters showed a gain of over 900 per cent. The total number of eggs received during the season was 20,480,000. a slight increase over the previous year. Of these 5,176,000 were delivered to Mr. G. H. Sherwood, an assistant in the Division of Scientific Inquiry, for experimental purposes, and from the remainder 12.857.000 fry were hatched. Of the fry 6,177,000 were delivered to Mr. Sherwood for rearing purposes, 2,462,000 were shipped to the Rhode Island Fish Commission, at Wickford, R. I., and the remainder were planted in the waters of Connecticut and Massachusetts.

During the year several collections of live fishes were made for the Pan-American Exposition and also for the aquarium at Central Station, Washington, D. C.

The usual repairs necessary at such a station were made during the season, as well as the necessary repairs to the vessels.

GLOUCESTER STATION, MASSACHUSETTS (C. G. CORLISS, SUPERINTENDENT).

During the summer months the station employees were occupied in overhauling and fitting up the cod-hatching apparatus, making repairs to the equipment and buildings, and also assisting in the construction of the new coal-house. The old coal-house, being past repairs, was torn down and a new one, 29 feet by 14 feet, with a capacity of 45 tons, erected in its place. After the cod season closed a woodshed 12 feet by 9 feet was built adjoining the coal-house, and all the station buildings were painted.

Early in November preparations were made for collecting cod eggs at Kittery Point, Me., and on November 15 Capt. E. E. Hahn, of the schooner *Grampus*, and a force of 7 spawn-takers reported there and at once began operations. The first eggs were taken and shipped to the station November 17. Eggs were collected daily until November 24, when bad weather put a stop to egg-collecting until December 6. Throughout December, January, and February the Ipswich Bay fishing was very poor and irregular. Cod were scarce and many of the boats were laid up for a week or two at a time, it often being difficult to find boats for the spawn-takers. The results of the collections were very disappointing, especially as the weather throughout the winter was exceptionally mild and favorable for fishing. The last eggs were taken March 20, and a few days later Captain Hahn and the *Grampus*

37

force proceeded to Woods Hole to fit up the vessel for collecting egg lobsters on the Maine coast. During the entire season 132,437,000 cod eggs were received at the station, of which 87,468,000 were collected at Kittery Point, Me.; 38,621,000 were received from the collecting station at Plymouth, Mass., and 6,348,000 from the Woods Hole Station. As a result of these collections 83,191,000 fry were hatched and distributed on the natural spawning-grounds from Ipswich Bay to Massachusetts Bay.

In the meantime preparations were being completed for collecting lobster eggs. Early in April collecting stations were established at Kittery Point, Me.; Boston, Mass., and Beverly, Mass., and the customary arrangements were made with fishermen and dealers for saving their egg lobsters. Collections were also made on the Maine coast from Wood Island to Eastport by the schooner Grampus, assisted by a steam smack which was chartered for the purpose. Active operations began April 18, when the first shipment of egg lobsters was received from Boston. The collections in April were unusually large. and in May were greatly increased, the collections at all the stations showing a substantial increase over those of the previous season. During June the collections in Massachusetts dropped off considerably. while at Kittery Point and along the Maine coast egg lobsters continued to be found in fair quantities up to the latter part of the month. The collecting stations at Boston and Kittery Point were closed on July 10. but the Grampus continued making collections up to July 18. The shipments of egg lobsters from the several collecting fields arrived at the station in excellent condition, with the exception of a few lots late in the season, the eggs on these being so far advanced that some of them were affected by the heat. The collections from all sources aggregated 5,901 lobsters, which yielded 83,418,000 eggs. Of the fry hatched from these 37,100,000 were distributed in Maine waters, 2,200,000 off the coast of New Hampshire, and the balance, except 180,000 sent to Woods Hole for experimental purposes, were planted at various points along the Massachusetts coast from Rockport to Boston.

CAPE VINCENT STATION, NEW YORK (LIVINGSTON STONE, SUPERINTENDENT).

During the year eggs of the white-fish, lake trout, brook trout, and pike perch were handled.

In November 3,771,000 green eggs of the lake trout were received from the Duluth Station which turned out very well, 2,347,600 fry being hatched from them and distributed. Later 4,088,000 green eggs of this species were sent from Charlevoix, Mich., but these turned out very badly, producing only 741,280 healthy fry.

In December 31,212,000 white-fish eggs were received from the Put-in Bay, Ohio, Station, and 10,003,000 from Detroit, Mich. Both lots turned out well, yielding, respectively, 27,346,000 and 6,954,000 strong, healthy fry.

During the months of January and February 816,250 brook trout eggs were received from commercial fish-culturists in Massachusetts, the product of which, as distributed, amounted to 749,350 fry.

In February 50,000 rainbow-trout eggs were received from Manchester, Iowa, resulting in 38,360 fry at the time of distribution.

In March an auxiliary station at Swanton, Vt., was established for the collection of pike-perch eggs. The superintendent assumed general charge of operations at this point, and was in the field in northern Vermont from March 27 to May 24. The run of pike perch up the Missisquoi River began unusually early, and trial hauls of the seine were first made on March 17. The first ripe eggs were taken April 7. The spawning season lasted fifteen days, during which time 113,550,000 eggs were taken, including the eggs contributed free of cost by the commercial fishermen on Lake Champlain. Most of the brood fish from which eggs were secured were captured by operating a seine on the Missisquoi River, and the green eggs collected from the fish thus taken turned out about 65 per cent of eved eggs. The total number of good eyed eggs, measured just before the hatching began. was 48,000,000, of which 32,000,000 were turned over to the State of Vermont, 11,925,000 were taken to the Cape Vincent Station, and the remainder, a little over 4,000,000, were distributed in the waters of Vermont and New Hampshire.

In the course of this work it was found that the use of muck is not essential for separating pike-perch eggs, the finely pulverized silt forming the upper layer of the river bed answering the purpose fully as well. It was also found that pike-perch eggs conveyed to the hatchery in the milt in which they were fertilized and put into jars immediately after being washed proved to be better than eggs treated in any other way.

Threen hundred steelhead-trout fry were liberated in the St. Lawrence River during the summer, the remarkable feature about this event being the fact that the fry were the product of eggs that had been taken from fish that had been hatched at the station four years earlier and had spent their entire life inside the hatchery building. The fry seemed strong and healthy. Several of the parents of these fish were subsequently liberated in the St. Lawrence River, together with some of the quinnat salmon, which had also matured in the hatchery building. Those of both varieties remaining in the hatchery were sent in September to the Pan-American Exposition at Buffalo.

During the year some minor repairs were made.

STEAMER FISH HAWK (JAMES A. SMITH, IN CHARGE).

The vessel arrived off Gloucester City, N. J., in the Delaware River, on April 29, and the hatching apparatus was immediately erected and spawn-takers from the vessel's crew detailed to attend the fishing shores at Howells Cove, Bennetts, and Cramer Hill. Having received information that the Pennsylvania Fish Commission would not operate the hatchery at Bristol, three spawn-takers were detailed to attend the fishery at Riverton, N. J., 9 miles above Camden. The first eggs were taken on May 1, but owing probably to the prolonged season of cool weather and the consequent low-water temperatures very little spawn was secured until May 14. Contrary to past experience, the majority of the spawning fish were found in the upper river above Philadelphia, and the fisheries below that point yielded very few eggs. Howells Cove, which has each season yielded the greatest amount of spawn, the take there last year amounting to nearly 50,000,000 eggs, produced this season only 6,500,000.

The collecting season ended on June 9, the total take of eggs aggregating 36,977,000. Of these 621,000 impregnated eggs were shipped to Central Station, Washington, D. C., and 25,997,000 fry were hatched; 4,835,000 of the fry were distributed on the spawninggrounds at Howells Cove and at the mouth of Timber Creek, New Jersey. The balance were planted by the regular car messengers in the waters of Connecticut, Massachusetts, New Jersey, Rhode Island, and Florida.

BATTERY STATION, MARYLAND (GEORGE H. H. MOORE, IN CHARGE.)

The station was opened March 24 by J. J. Glennan, who, with a small force of men, prepared the buildings and apparatus for active operations. The superintendent assumed charge of operations on April 21, and the first shad eggs were received April 22. The total collections of eggs for the season, which ended June 5, amounted to 20,707,000. Of these, 2,134,000 were shipped to the Exposition at Charleston, S. C., which were subsequently hatched and distributed from that point. The balance, with the exception of 267,000 sent to Central Station, were hatched and produced 14,943,000 fry.

As at the other shad stations, ripe fish were scarce, and it is a notable circumstance, as reported by old and experienced fishermen, that while the proportion of roe or egg-bearing fish was greater than usual, the percentage of ripe fish was smaller than ever before noted by them.

A supply of herring roe was canned and shipped to the stations at Wytheville, Va., and Erwin, Tenn., to be used as food for trout fry.

A few cases of shad roe were canned with a view to testing its edible qualities. From those who have tested it many favorable reports have been received, and it is the consensus of opinion that it would be difficult to distinguish it from the fresh roe. The method pursued in its preparation and preservation is simple. After being washed a set or pair of roe are put in a 2-pound tin can, which is then capped, exhausted, tipped, and subjected to 15 pounds steam pressure for about an hour. To prepare for the table it is removed from the can and cooked the same as the fresh roe. The milt has also been successfully canned, and it is quite as palatable as the fresh product.

The following table shows the details of operations:

| Operations a | t Battery | Station in | 1902. |
|---------------------|-----------|------------|-------|
|---------------------|-----------|------------|-------|

| Date. | Number of eggs when received. | Number of eggs 12 hours after received. | Number of eggs24 hours after received. | Number of eggs 36 hours after re- ceived or number pur- chased. | Fry hatched and planted. | Number of eggs shipped. | Mean water tempera- ture |
|-----------------------|-------------------------------------|--|---|--|--------------------------------|-------------------------------|-----------------------------------|

BRYAN POINT STATION, MARYLAND (L. G. HARRON, IN CHARGE).

The old pump-house being badly out of repair and disadvantageously located with reference to the new hatchery, a new and substantial pump-house was erected near the east end of the hatchery and the suction pipe extended from the pumps to the river on the bracing under the new wharf to a point where the water is 10 feet deep at low tide. This change in the location effected the saving of 248 feet in the length of the discharge pipe from the pumps to the supply tank, with a resultant saving in fuel whenever the pumps were operated. The boiler and pumps were removed to the new pump-house, and the old pump-house was fitted up as quarters for four of the spawn-takers; 354 feet of 3-inch discharge pipe was removed from underground, and 106 feet of the same relaid; 240 feet of 3-inch suction pipe was also laid, and the necessary steam-pipes connected. A suitable coal-bin was constructed adjoining the pump-house. The launch *Blue Wing*, which had been ordered from Woods Hole, Mass., arrived at Washington on March 23 and was taken to Bryan Point the following day. Some necessary repairs were made on her stern post and her hull above the water line, and all her house work and decks were thoroughly cleaned and painted, after which she was in good condition for the season's work.

The station was opened March 24. Sixteen tents were set up and the necessary equipment installed therein for quartering spawn-takers. The hatchery and other buildings were painted with a coat of indurine, and by April 15 all necessary repairs were completed preparatory to active operations in collecting shad eggs.

Small lots of eggs were taken on April 15, 16, and 17, which were placed in jars, but they died and no record was kept of them. On April 18th 60,000 good eggs were received, and on April 20th 791,000 eggs were taken and fishing began in earnest, the entire force of spawntakers being set to work. The collecting of eggs was pushed vigorously with a full force until May 9, when operations were discontinued. The total collection of eggs for the season was 45,971,000, of which 2,421,000 were shipped to Central Station, Washington, D. C., and 2,007,000 were shipped to the Fish Commission exhibit at Charleston, S. C. Of the 41,543,000 eggs remaining, 84 per cent, or 34,994,000, were hatched at Bryan Point. Of the fry resulting 9,018,000 were delivered to the Fish Commission cars at Alexandria, Va., for distribution in southern waters, and 25,976,000 were planted on the principal spawning-grounds in the Potomac River.

The following table shows the daily collection of eggs, the number of fry planted, and maximum and minimum water temperatures:

REPORT OF COMMISSIONER OF FISH AND FISHERIES.

FISH LAKES, WASHINGTON, D. C. (C. K. GREEN, SUPERINTENDENT).

The station being located within the parking system of the District, much attention is given to the ornamentation and care of the grounds during the summer. During the summer months the work consists chiefly in keeping down the extensive growth of aquatic grasses in the various ponds and giving them a tidy appearance. The adult bass and crappie are fed regularly, the food consisting of carp bred for the purpose, which are taken from the ponds by means of nets, dressed, and cut in pieces as large as a hickory nut for the adults and from one-fourth to one-half this size for the yearlings. In the fall of the year, when the breeding-ponds are drawn, a supply of young carp is secured and introduced into the stock ponds, and in this way the adult fish are furnished with a food supply throughout the winter.

During the year the cottage was thoroughly renovated and put in a sanitary condition as a residence for the superintendent. The work of collecting young fish for distribution was begun September 16 and continued until October 21, the total number furnished consisting of 4,688 large-mouthed black bass, 17,468 crappie, and 30,000 cat-fish. On October 18 the shad which had been introduced as fry the previous May to the number of 2,000,000 were liberated in the Potomac River by raising the gates leading from the pond to the river. Several specimens examined when liberated showed that the fish had grown to an average length of $3\frac{3}{4}$ inches.

The usual attention was paid to the cultivation of ornamental fishes, such as gold-fish, golden tench, green tench, and golden ide, which are raised for stocking the aquaria at the Zoological Park and Central Station and for the District parks. Large numbers of carp were also reared for fish food. Many predatory animals, birds, and snakes were killed during the year.

The crapple began spawning April 17, in a water temperature of 61°, and continued until May 15, the height of the season being about May 2, when the temperature of the water ranged from 68° to 75°. The first eggs cast hatched in five days, the water temperature during the time ranging from 53° to 66°, but as the weather became warmer the period of incubation was reduced to three days.

The large-mouthed black bass began spawning April 20, in a water temperature of 64° , and ceased spawning about May 20, although four nests were discovered between June 2 and June 13. The height of the spawning season was about April 23, when the water temperature averaged about 71°. The first fry made their appearance April 24.

CENTRAL STATION, WASHINGTON, D. C. (J. E. BROWN, IN CHARGE).

The work at Central Station has been conducted on the same lines as for the past few years. The station is used as a clearing-house for much of the product of the Fish Lakes Station and for shipments of fish and eggs sent here from other stations. During fall and winter various species of fish are hatched for the purpose of illustrating the methods of fish-culture. This branch of the work has always formed an attractive and very interesting exhibit.

Following is a record of the fish and eggs received at the station during the year, eggs hatched, and fish distributed:

| Species. | Fish received. | Eggs received. | Eggs shipped. | Eggs hatched. | Fry shipped. | Fish shipped. |
|-------------------|-------------------|-------------------|------------------|------------------|-----------------|------------------|
| Black bass | 787 | | | | | 787 |
| Rock bass | 2,300 | | | | | 2,300 |
| Rainbow trout | 1,746 | 9,823 | 100.000 | 7,120 | 4,200 | 1,741 |
| Lake trout | | 253, 925 | 160,000 | 58,512 | 53,200 | |
| Brook trout | | 9,729 | | 9,117 | 8,000 | |
| White-fish | | 3,099,000 | 2,138,000 | 628,000 | 600,000 | |
| Atlantic salmon | | 10,000 | 5,000 | 4,620 | 4,050 | |

| Total | 4,833 | 8, 279, 477 | 2,703,000 | 4,561,780 | 4, 323, 320 | 4,828 |

CENTRAL STATION AQUARIUM (L. G. HARRON, SUPERINTENDENT).

In addition to his regular duties in charge of the aquarium at Central Station, the superintendent was detailed to the station at Woods Hole, Mass., from July 8 to August 15, for the purpose of superintending the arrangement and stocking of the aquarium there. In February he was detailed to superintend the installation of a live-fish exhibit at the Sportsmen's Show in Boston, and from March 24 until May 14 he was detailed in charge of the shad hatchery at Bryan Point.

During the summer the aquaria were kept well stocked with the various species of fresh-water fishes found in the Potomac River and five species of ornamental fishes, some of which have been kept in the aquarium for years. In the fall, as soon as the water temperature was sufficiently cool to maintain them, various species of *Salmonidæ* were introduced into the aquarium and carried through the winter. An assignment of trout, salmon, and grayling, representing nine species, was received from the aquarium at Buffalo, at the close of the exposition, and held until December, when the stock was drawn upon to stock the Fish Commission exhibit at the Charleston Exposition.

A live-fish exhibit of marine species was maintained in the aquarium from September until May 15, when the salt-water exhibit was given up entirely, and the closed circulating system connected with this exhibit was used for supplying the fresh-water aquaria, which were cleaned out and completely stocked with fresh-water fishes. The adoption of closed circulation for supplying fresh water is an experiment to test the feasibility of using the system of closed circulation for this purpose at the St. Louis Exposition in order to insure having perfectly clear water in the aquaria at all times. At the close of the year this system was in successful operation, and the exhibit showed great improvement over its appearance when the filthy water of the Potomac was supplied to the aquarium from the city water mains. Very few improvements have been made to the aquarium in the past few years, and in comparison with the elaborate aquarial displays at the World's Fair in Chicago and the Pan-American Exposition at Buffalo the Central Station aquarium is a very small affair. It should be greatly enlarged and the salt-water tank supplemented with an additional one, so that during the year, while the stock of marine species is in the aquarium, the salt water can be entirely renewed every few months. A refrigerating system is also recommended, in order that the various species of the *Saluonidæ* may be carried in the freshwater aquaria during the summer months.

The following is a list of the marine and fresh-water species exhibited at Central Station during the year:

Salt-water species.—Jumping mullet, croaker, hog-choker, red drum, sea-robin, toad-fish, sea trout, moon-fish, pompano, swell-fish, spot, pin-fish, spade-fish, blue-fish, yellow-tail, king-fish, striped bass, tautog, flounder, white perch, tongue sole, crevalle, sea bass, blenny, pig-fish, file-fish, scup, rudder-fish, cunner, bur-fish, tom-cod, remora, mumnichog, star-fish, chaetodon, conger eel, blue crab, hermit crab, lobster, sea-anemone.

600, renora, informaterog, startach, encend, congr. Correct, and construction of the search of th

WYTHEVILLE STATION, VIRGINIA (GEORGE A. SEAGLE, SUPERINTENDENT).

Fish-cultural operations have been confined chiefly to the propagation and distribution of rainbow trout, brook trout, black bass, and rock bass. The number of fish on hand at the beginning of the year is shown by the following table:

| | Calendar year in which fish were hatched. | | | | | | |
|--|---|-------|-------|-------|---------------------|--|--|
| Species. | 1901. | 1900, | 1899. | 1898. | 1897, or before. | | |
| Rainbow trout Brook trout | 318,000 19,400 | 5,080 | 598 | 339 | 1,872 | | |
| Large-mouthed black bass Small-mouthed black bass | | 112 | | | 53 | | |
| Carp | | | 39 | 80 | 11 180 20 | | |
| Gold-fish | | | | | 15 | | |
| Total | 337, 400 | 5,192 | 637 | 419 | 2, 151 | | |

45

The distribution of the stock of young was begun October 5 and continued until December 13, the output amounting to 208,100 yearling and 385 adult rainbow trout, 13,124 brook trout, 3,815 black bass, 8,700 rock bass. In addition to the above the following fish were received from other stations and distributed: 3,450 brook trout, 2,142 black bass, 9,650 rock bass, 7,310 crappie.

The spawning season of the rainbow trout began November 6 and closed February 10. During this period of ninety-seven days 1,099,000 eggs were collected, of which number 802,000, or 73 per cent, were fertilized and brought to the eyed stage, 246,000 were shipped on assignment, and 556,000 were hatched at the station. The fry resulting from them were strong and vigorous, and when four months old 145,000 were distributed to various applicants by the station employees, and at the close of the year there remained on hand 200,000 fingerlings to be reared for the fall distribution.

In January 304,000 eyed brook-trout eggs were received from one of the commercial hatcheries at Plymouth, Mass., in good condition and hatched out well. Owing to an unusual period of muddy water during the hatching stage, there was a loss of 18,000 alevins, caused by smothering, and the mortality among the young fish during the sac stage was considerable, presumably from the same cause. The fry began feeding when about four weeks old and have grown rapidly. At the close of the year there were 105,000 fingerling fish on hand, the largest weighing 134 ounces to the thousand. The brook and rainbow trout fry were fed on canned herring roe for the first six weeks, when the food was gradually changed to a mixed diet of liver and mush.

Early in the spring the brood stock, consisting of 53 large-mouthed and 11 small-mouthed black bass, were transferred to the breeding ponds. Large beds of creek gravel were provided for their nests, and a light paling fence was built around the nesting-ground to keep the brood fish within its limits. The fish commenced nesting early in May, and by the middle of the month several large schools of young were observed. When the fish were from one-half to five-eighths of an inch in length, which is about the time of the breaking up of the schools, a few thousand were netted from the ponds and placed in rearing-troughs for the purpose of making some experiments in artificial feeding. These fish were first given minute insects collected from the warm, shallow parts of the pond. Only enough of this natural food was given to keep them alive, and while their appetites were only partly satisfied in this way, prepared artificial food was offered them. Ground fish, crawfish, beef heart, and herring roe were all tried, but the experiment was not sufficiently successful to warrant continuing it for more than a few days. If crawfish could have been secured in sufficient quantities, it is believed that better results would have followed, as the fish preferred it to the other food. As soon as it became evident that the experiment would not be successful the fish were released in rearing-ponds, together with several thousand more which had been captured from time to time.

About two weeks later, when the fish were nearly an inch in length, the experiment was repeated by transferring 1,500 bass from the ponds to a trough. This time the fish were easily trained to take artificial food. They were first given chopped or ground fish, and afterwards prepared beef heart. After the first two or three days they devoured this food ravenously until about the tenth day, at which time they began to die, and although eating well and apparently in the best of health, the death rate steadily increased from day to day, until the loss reached over 100 per day. On the fourteenth day the remaining fish in the trough, about 900, were released in the rearing-ponds. The cause of the mortality is not known, but sufficient success followed the feeding of artificial food to warrant taking up the experiments another season, in the hope that the cause of the mortality would be ascertained.

The brood stock of rock bass were transferred to their summer ponds about the middle of April, and nesting began the latter part of the same month. By the middle of May the ponds were well stocked with young fish, and at the close of the year there is every prospect of a large crop.

The following improvements at the station were made during the fiscal year: The superintendent's residence was painted, a water tank for supplying the transportation cars with water at the railway siding was erected, and pipe connections made with it and with a Rife hydraulic ram for supplying the tank with water. A cooling tank for mush and two tanks for culling fish were also constructed, besides several other minor improvements.

Edenton Station, North Carolina (S. G. Worth, Superintendent).

This is one of the new stations, all constructions having been made since 1899. It is in first-class condition as a shad-hatching station, the third successive season of operations having this year been concluded.

Within the year two tidal ponds were constructed, which will demonstrate the value of this class of ponds for producing black bass and crappie for stocking interior waters. The bottoms of these ponds are from 3 to 5 feet below the surface of Pembroke Creek, wire screens in the gateways permitting such change of water as the irregular wind tides send in or draw out. The ponds can be emptied when desired at the rate of 1,200 gallons per minute by means of a centrifugal steam pump economically operated.

The shad-hatching season of the present year was marked by its short duration, being practically confined to twenty-two days between April 14 and May 8. Adult shad were less abundant than usual by one-half. It is believed by the station superintendent that this scarcity was caused by the destruction of the young in the prolonged and violent hurricane which beat directly upon the Atlantic coast August 18-21,

48 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

1899. The young which should have arrived at maturity and reentered the sounds and rivers in 1902 were then but a few inches long and were outside the inlets and subject to the breakers.

The spring was very late, both air and water being far below the normal temperature.

A feature unobserved before in this region was the deposition of eggs by the shad 20 miles or more down the sound to the eastward of Edenton Bay. The superintendent attributes this new condition to the excessive rainfall of the previous year, which freshened the waters of Albemarle Sound throughout its length, consequently when the shad reached the fisheries where the spawn-takers were located they were largely spawned out or were carrying overripe eggs owing to low temperatures. A large percentage of loss followed in the process of hatching the eggs.

The whole number of eggs brought to the station was 37,987,000, and from these there was a production of 24,662,000 young fish, the liberation of which is shown in the table of distribution.

ERWIN STATION, TENNESSEE (ALEX. JONES, SUPERINTENDENT).

The fingerling fish on hand at the beginning of the year were distributed as yearlings during the fall and winter, 49,670 being supplied to applicants in eastern Tennessee and western North Carolina by the regular employees of the station. The remainder were shipped by the Fish Commission cars to more distant points. The total product of the station for the season amounted to 133,925 yearling rainbow trout, 12,075 yearling brook trout, 1,050 black bass.

The brood rainbow trout began spawning on November 12 and continued to February 7, the total collections of eggs being 329,100. There were also received from Wytheville Station 50,000 rainbow-trout eggs, and from Neosho 171,740 rainbow-trout eggs. This stock of eggs produced 280,000 fry.

The purchase of 200,000 brook-trout eggs was made from a commercial hatchery in Massachusetts and produced 164,180 fry.

The rainbow trout were transferred from the hatchery to outside ponds as soon as they began to feed nicely, and they grew rapidly with little or no mortality until the approach of warm weather in April. At this time they were attacked by a peculiar disease, and until the warm weather was over there was an unusual mortality among them. This disease is not fully understood, and no remedy has yet been found for it. The first symptoms may be described as follows: Contraction of the stomach, general weakness, rising to the surface with spasmodic contortions, and inability to take food, although inclined to do so. Microscopical examinations failed to reveal any signs of affection of the stomach, throat, or gills, although the latter were at times greatly inflamed. The disease attacks the fish whether in the hatchery or outdoors, in deep or shallow ponds, and with or without shade, but the trouble is most apparent during and immediately following very hot weather. It abates during cool days, even though the variation in temperature may not be more than four to six degrees.

The young fish at this station are fed on beef liver and canned herring roe, the beef to the brook trout and the roe to the rainbow trout. The brook trout do not seem to be able to masticate the roe, but the rainbows are especially fond of it, and it has proved a very economical and nutritious food for them for a period of about six weeks, after which time it has been found best to change their food to liver.

Predatory birds and animals are exceedingly numerous and destructive in the summer months, and great numbers are annually destroyed.

The following table shows the stock of fish on hand at the close of the year:

| Constant of the second s | Calendar year in which fish were hatched. | | | | | | |
|---|---|-----------|-------|-------|----------|--|--|
| Species. | 1902. | 1901. | 1900. | 1899. | 1898. | | |
| Rainbow trout Brook trout | 66,000 | | | | | | |
| Rock bass Black bass Crappie. | | 75 696 | | | 54 25 | | |
| Total | | 2,682 | | | 1,394 | | |

By an act of Congress \$5,000 became available in March for the completion of the station, new ponds, and other improvements, and work was immediately commenced on the construction of three ponds ranging in size from 1 to 2 acres, and these have been completed. Another pond 1 acre in area, which had already been partially constructed, was completed. Various repairs and improvements were made about the station buildings, roadways were constructed from the hatchery to the main highway, and 50 shade trees were set out. Contracts have been made for a substantial fence around the station property, and at the close of the year it is in course of construction.

COLD SPRINGS STATION, GEORGIA (J. J. STRANAHAN, SUPERINTENDENT).

Within the year the construction work under the special appropriation was of minor importance, but with it the station was practically completed. There was erected near the station residence a woodhouse 16 by 20 feet, a cabin was built for one of the laborers, and three bridges were constructed across Cold Springs Creek. The drives, walks, lawns, and embankments to the ponds were graded, and the lawns and pond embankments seeded down. All rubbish and underbrush were removed, so that the station presents a neat and attractive appearance. The fish-cultural work was confined to the propagation of the large-mouthed black bass, bream, crappie, and speekled cat-fish.

The spawning season of the black bass extended over 110 days, and this year the season began a full month earlier than in former years, notwithstanding the fact that the temperature of the water was cooler

F. C. 1902-4

for the month preceding and during the spawning time than in any year since the establishment of the station. With a few exceptions the bass finished spawning two months earlier than usual. But few eggs were deposited by them in any of the ponds as compared with former years, although the output of young fish was much greater, owing to improved facilities, a larger stock of brood fish, and an earlier distribution.

Pond culture at this station is still in the experimental stage, as the conditions here are not the same as those existing at other stations. The chief difficulty presenting itself is that of fish food. Very little aquatic or plant life is found in the waters under natural conditions, and it is difficult to make the introduced plants thrive and thereby increase the amount of natural food by the development of aquatic life which would naturally follow. The output of black bass fingerlings has, however, been much greater than in previous years, and it is expected that the product of the station can be annually increased for several years to come.

The young bass removed to the fry ponds were fed on chopped fish raised at the station, and no mortality resulted from what appeared to be convulsive fits, which caused an alarming mortality last year when the young fish were fed upon salt-water mullet preserved by some apparently injurious chemical. By careful sorting cannibalism was reduced to a minimum throughout the season. The product of the station in fingerling fish is recorded as follows: Black bass, 13,310; bream, 17,350; speckled cat-fish, 5,850. At the close of the year the stock of young fish on hand available for distribution as fingerlings is estimated as 5,000 bream, 40,000 cat-fish, and 10,000 black bass. There are also on hand a few hundred calico bass.

PUT-IN BAY STATION, OHIO (S. W. DOWNING, SUPERINTENDENT).

In addition to various minor repairs at the station the wharf was rebuilt to the water's edge and covered with 2-inch oak plank; the channel and harbor were also improved by dredging the channel to a depth of $9\frac{1}{2}$ feet and widening it 25 feet. This enlargement gives ample room for the crates used for holding the white-fish penned during the spawning season.

In the fall the work of collecting eggs of the white-fish was pushed at all the fields customarily operated from the Put-in Bay Station. On October 20 a crew of men was set to work at Monroe Piers, Michigan, and two additional rafts of 5 crates each were constructed, making a total of 30 crates available. On this shore the prevailing winds were unfavorable throughout the season, and but 6,627 fish were received at the crates, a few more than one-half the number penned at this point the previous year. Part of these were penned in October, and the temperature of the water during the latter part of the month was so high that a large number of the fish were returned to the fishermen before spawning commenced. As a further result of the warm weather

REPORT OF COMMISSIONER OF FISH AND FISHERIES. 51

quite a number of the females became plugged, causing the yield of eggs from the number of fish penned to run below the average.

At Put-in Bay the first fish were received at the crates on October 22 and by the 30th of October 1,403 fish had been received. Owing to the warm weather nearly all the fish taken at this time had to be returned to the fishermen, and penning was discontinued until November 5, when it was commenced again and continued until December 1. The total number collected and penned after November 5 was 5,963 fish, nearly one-fourth of which had been returned to the fishermen before the spawning season commenced. The final results of the work at this point, however, were very satisfactory. At the Port Clinton field men were set at work on November 6 and at the Kelley Island and North Bass fields on November 11. Although the weather was rough and unpleasant through the greater part of the season, there were but few days on which the fishermen did not visit their nets, and the number of eggs secured was beyond all expectations, more than 100,000,000 in excess of any previous season's collection being taken.

The number of eggs received from the different fields and from the crates was 335,860,000, as follows:

| · Locality. | Field. | Crates. |
|--|--------------|---------|
| Monroe, Mich. Put-in Bay. North Bass. Kelley Island. Port Clinton. Total. | 47, 516, 000 | |

The increased collections were particularly noticeable at the Port Clinton and Kelley Island fields, the first yielding nearly twenty-five times as many eggs as last year, and more than twice the number taken in any season since 1895, when 92,000,000 were secured. At the Kelley Island field the yield was more than four times greater than ever before, and at North Bass it was twice as large as the greatest take of any previous season. At Put-in Bay the yield was four times greater than last year.

The first eggs were received from the fields on November 12 and the last December 2; the first collections from the crates arrived on November 13 and the last December 7. A shipment of 48,160,000 eggs was made to the Pennsylvania fish-hatchery at Erie, Pa., and 31,212,000 were transferred to Cape Vincent; 256,488,000 were retained at the station until eyed, when 8,100,000 were shipped to the New York Fish Commission and 1,000,000 to the Central Station at Washington, the balance being retained for hatching.

During the early stages of development every jar in the hatchery was filled, the surplus of eggs being cared for in floating boxes placed in the fry tanks until arrangements had been made with Col. Horace Park, superintendent of the Sandusky, Ohio, hatchery, for the loan

of 100 jars of the Chase pattern. The borrowed jars were operated by tapping the fry tanks and using wooden faucets, the jars standing upon the floor, and in this way the surplus eggs were cared for until the natural losses and the shipments to other stations made room for all the eggs in the regular batteries.

The eggs commenced hatching on March 25 and were all out by April 15, the period of incubation being 128 days. Eighty-two per cent of the eggs retained were hatched, giving a total of 200,500,000

The Downing jar.

fry, which were liberated in the waters of Lake Erie.

Preparations were made for the collection of lake-herring eggs and a force of men sent to Ashtabula, Ohio, where large catches of herring had been reported, but up to very late in the season very few female fish were taken and none of these were spawning. On December 6 the weather turned so cold as to make large fields of ice, and as there seemed to be no prospects of continuing the work the men were ordered home and the efforts to secure herring eggs were discontinued.

On April 2 men were placed in the Toledo, Ohio, and Monroe, Mich., fields for the collection of pike-perch eggs, and on April 6 pike-perch work was also taken up at Port . Clinton, Ohio. Although the weather turned cold, the spawn-takers were very successful in securing eggs, the total collections amounting to 437,200,000, the greatest number with one exception ever secured in one season at Put-in Bay Station. The first eggs were received April 4 and the last April 19, the total yield from the various fields being as follows: Toledo field, 246,850,000; Port Clinton field, 126,800,000; Monroe field, 63,550,000.

Of these eggs 66,000,000 were shipped to State fish commissions and on other assignments, leaving a balance of 371,200,000 on hand to be hatched at the station. Of those retained 48 per cent hatched, and the resulting 143,000,000 fry were disposed of as shown by the tables of distribution. The loss on the eggs was much greater this season than last, being 52 per cent as against a record of 34 per cent the previous year. As the same spawn-takers were employed this year, and the methods were the same as last year, the only possible way to account for the greater loss is the difference in the temperature of air and water, the weather remaining cold and disagreeable through-

REPORT OF COMMISSIONER OF FISH AND FISHERIES.

53

out the entire period of incubation, thus causing the eggs to develop very slowly. Hatching began May 3 and closed on May 12.

The superintendent was given authority to make some experiments with the view to making improvements in the form of hatching jar, having in mind convenience in manipulation and general results. Accordingly, a jar was designed somewhat after the pattern of the Chase jar, except that it has a glass instead of a metal spout and is made smaller at the top than at the bilge, thus concentrating the current of water and giving a good motion to the eggs at the top as well as at the bottom. The new jar was received January 18 and a poor lot of eggs placed in it. It was found that these eggs cleaned up faster in the new jar than in any of the older forms, that about a quart more eggs could be worked in it than in either of the other jars, and that it required but two-thirds the volume of water required in the older forms. From an economic standpoint and for convenience in handling it is claimed by the superintendent to be far the best jar used at the station.

NORTHVILLE STATION AND SUBSTATIONS IN MICHIGAN (FRANK N. CLARK, SUPT.).

In the output of eggs and fry the past year's operations at the stations in Michigan have been the most successful of any since the commencement of the work. There are two regular stations in the State, one at Northville and the other at Alpena, and in addition to these the hatcheries at Detroit and Sault Ste. Marie, belonging to the Michigan Fish Commission, have been operated the greater part of the year, Northville Station being the headquarters.

At the beginning of the year there were no fish or eggs in the Northville hatchery, and the number of fish in the ponds was very small. For the first two or three months, therefore, the force were engaged in preparing for the reception of eggs, maintaining the buildings, ponds, and grounds, and in construction work.

Three old wooden ponds were torn out, and in their place two cement ponds 50 feet long, 8 feet wide at the surface, and 6½ feet wide at bottom were constructed, the cement being 5 inches thick on the sides and 4 inches on the bottom. These ponds are supplied with water from a spring under the hatchery, which flows about 135 gallons per minute, the temperature being 48° F. They were constructed for experimental work in connection with the bacterial disease that has caused great mortality amongst the brook trout in past years. Fish not affected by the disease were brought from the Au Sable River and introduced into the ponds.

The experimental work is being conducted under the direction of Mr. M. C. Marsh, and further mention of it is contained in the report of the Division of Scientific Inquiry.

Six old ponds with plank sides were also torn out with the intention of replacing them with one large pond, which will cover more surface than the old ones.

About October 20 preparations for the collection of lake-trout eggs were commenced. After the superintendent had visited various points with the view of establishing field stations it was decided to confine operations to Beaver Island and Manistique, on Lake Michigan, and arrangements were completed for the conduct of work after the close season, which began October 30, on practically the same lines as in previous years, the fishermen agreeing to bear all expenses of catching the fish, and to receive the fish so caught in compensation for their services after the eggs had been taken by representatives of the Commission.

At the Beaver Island group the tugs fished on the shoals within a radius of 33 miles from the harbor of St. James, which is about 36 miles from the mainland, without telegraphic communication, and in rough weather without a regular boat service. The most important of the fishing-grounds were Boulder Reef, Skillagillee, West Shoals, Trout Island Reef, and The Hat, the largest number of eggs being obtained at Boulder Reef. All spawning fish were captured in from 3 to 26 fathoms of water, the early run being principally in water from 9 to 18 fathoms deep, and the last run, which were larger trout, in from 18 to 26 fathoms of water. The first fish were captured November 3, and the last on November 30. The collections were not notably large until November 13, but from that time on to the close of operations the work was highly successful, the best results being secured from November 18 to 26, inclusive. In all, 13,670 trout, weighing 103,716 pounds, or an average of nearly 7³/₄ pounds each, were captured, and from them 14,804,000 eggs were taken.

At Manistique all eggs were taken between November 5 and 27, the season being a triffe later than usual owing to warm weather. At this point 11,937 trout, weighing 72,796 pounds, were captured, which produced 10,508,000 eggs.

Of the 25,312,000 lake-trout eggs obtained at these two points 14,304,000 were shipped to Northville. The remainder were transferred to the Alpena, Sault Ste. Marie, and Cape Vincent stations. After the eggs sent to Northville were eyed, 5,305,000 were distributed to various points and the hatching period of the balance extended from February 17 to March 25. All of the fry, with the exception of 700,000 distributed in inland waters, were deposited in the Great Lakes and were in excellent condition when planted.

Brook-trout eggs to the number of 1,074,000 were purchased from commercial hatcheries in Massachusetts, and in addition to these 41,807 were taken from the adult fish in the ponds at Northville, making a total of 1,115,807 brook-trout eggs. Of these 1,055,000, or a little over 93 per cent, hatched, the first fry making their appearance on

55

January 28. The hatching season closed on March 5, and the distribution of fry was made during March and April by the Fish Commission cars and was very successful.

From the brood stock of Loch Leven trout 78,000 eggs were taken, the first on October 28 and the last December 12, the 117 females stripped averaging 667 eggs to the fish. These eggs were of extra fine quality, and from them 75,000 fry were hatched and planted, a trifle over 96 per cent. They were the first eggs in the house to hatch, beginning January 4 and continuing until February 25. The distribution of the fry was made between March 12 and 18.

From the Neosho and Manchester stations 105,012 rainbow eggs were received, from which 86,000 fry, or about 82 per cent, were hatched and planted. This low percentage was due to the fact that some of the eggs were not in good condition when received. The first eggs hatched February 19 and the last March 12, and by April 17 the distribution of the fry had been completed.

From a stock of 3-year-old steelhead trout, which had been hatched and reared at the station, 114,600 eggs of fine quality were obtained, the first on March 19 and the last on April 10, the females averaging 850 eggs each. In addition to the above 50,000 steelhead eggs were received on April 8 in good condition from the Clackamas, Oreg., Station, making a total of 164,600. They commenced hatching on April 23 and closed on May 6, when 140,000 fry, or 85 per cent, were hatched and distributed shortly afterwards in good condition.

One of the finest consignments ever received at the Northville Station arrived from the Bozeman, Mont., Station on May 16, the case containing 209,078 grayling eggs. These were placed in spring water, and in a few days practically all hatched, and shortly afterwards the resultant fry were planted in excellent condition.

At the Alpena Station hatching operations began on November 20, when 35,000,000 green white-fish eggs were received from the Detroit hatchery, and on December 6 a second shipment of 16,000,000 arrived. From the 51,000,000 eggs thus received 42,500,000 fry, or nearly 84 per cent, hatched. The eggs began hatching April 6 and finished April 18. The distribution of the fry was commenced April 11 and was completed April 22, all of the plants being made in Lake Huron, with the exception of 500,000, which were sent to Turtle Lake.

In addition to the white-fish eggs sent to the Alpena Station, 3,581,000 lake-trout eggs were transferred there from Northville and Manistique at various times in the course of the season, and it became necessary to construct additional hatching-troughs to accommodate them. In the month of April 2,530,000 lake-trout fry were distributed, most of them being planted in Lake Huron not far from the Alpena Station. At this point during the past fiscal year a greater number of fry, both of lake trout and white-fish, have been turned out than ever before, the fry being of the most excellent quality.

At the Detroit Station the work has been confined entirely to whitefish operations, the eggs being collected from the field stations on Belle Isle and Grassy Island, the former located in the Detroit River opposite the upper end of the city of Detroit, and the latter about 8 miles down the river below the city. Fishing was conducted by means of seines, the work being done by the Wolverine Fishing Company, which received the fish in payment for its services after the agents of the Commission had taken the eggs. The fishing season extended from October 16 to December 3, during which time 2.875 hauls of the seine were made and 41,242 fish captured—an average of between 14 and 15 per haul. Of these 2.270 were undersized and were immediately returned to the river. The remaining 38,972 were retained in crates and pounds. The crates used in this work were constructed of slats, to allow free circulation of water, and were 12 feet long, 4 feet wide, and 5 feet deep. The pounds, which were irregular in size and shape, were made by driving boards into the bottom of the river, with a space between each for the free circulation of water. The best day's fishing was on November 18, when 2.568 fish were caught. Of the fish held, 22, 245 were males and 16, 727 females. Of the latter, 12, 529 were stripped, vielding 366.040,000 eggs, or an average of 29,215 per fish. The balance of the females were either spent, plugged, or hard when the season closed.

Following is a summary of the daily take of eggs:

All of the eggs were forwarded to the Detroit hatchery by means of tug and wagon, it being necessary to hold over night those taken at Grassy Island, but this was done without detriment. The number of eggs shipped was 201,800,000, leaving 164,240,000 in the hatchery. As the total number hatched was 135,000,000, it would appear that the percentage was a little above 82, but in reality it was about 85 per cent when allowance is made for the fact that a part of the eggs shipped were eyed eggs. The season was rather earlier than usual, the hatching period extending from March 23 to April 16, and the distribution was made between March 30 and April 17 by means of a' tug and two of the Fish Commission cars. The cars carried 27,000,000 fry in five loads, three of 5,000,000 each to Charlevoix and two of 6,000,000 each to Mackinae City, for planting in Lake Michigan. The balance were deposited in the Detroit River and Lake St. Clair.

Not only did the number of white-fish greatly exceed that of any previous year, but the quality of the fry also greatly surpassed that of any of the earlier efforts. This may have been due in part to the favorable weather conditions, improved facilities, and expert manipulation, but undoubtedly credit should be given to the liberal plants made in the past in the Great Lakes.

To relieve the overcrowded condition of the Northville and Detroit stations, and also to comply with the Milliken act of the State legislature, which provides that the fry from 75 per cent of the eggs collected shall be deposited in State waters, the Sault Ste. Marie hatchery was used, and from the 16th to the 23d of November 5,000,000 laketrout eggs were sent there from Manistique. Of the 3,700,000 fry which hatched from these eggs, 1,000,000 were turned over to the Michigan Fish Commission and 2,700,000 distributed. The eggs began hatching April 20 and it was not until May 10 that all had hatched, the cold weather greatly retarding development, although it apparently made the fry extremely hardy. The first plant was made on May 19, and the last of the fry were liberated May 31, the work being done by messenger and tug.

A shipment of 30,000,000 white-fish eggs was received at the Sault Ste. Marie Station from Detroit on November 29th, 6,080,000 on December 28, and 10,000,000 on February 25, or a total of 46,080,000. The first shipment was made when the eggs were green and the last two shipments after the eggs were eyed. The product of the eggs resulted in 40,000,000 fry, or about 86 per cent, the first hatching on April 10 and the last on April 29. With the exception of 2,000,000, which were shipped by baggage car to Manistique, the distributions were all made by boat. The first plant was made on April 15, and the work of distribution was completed on May 1. A large proportion of the fry were planted in Lake Superior near Whitefish Point and in Lake Huron off Detour.

57

The Commission is indebted to A. Booth & Co. for the free transportation of fry to Whitefish Point, Lake Superior.

The following table shows the number of eggs collected, number of eyed eggs shipped, and fry distributed:

| Species. | Eggs collected. | Eggs shipped. | Fry distributed. |
|--|--|------------------|--|
| White-fish . Lake trout. Brook trout Steelhead trout Rainbow trout Loch Leven trout Grayling | $\begin{array}{r} 25,312,000\\ 1,134,260\\ 164,600\\ 105,012\\ 78,000 \end{array}$ | | $\begin{array}{c} 217, 500, 000\\ 13, 255, 000\\ 1, 055, 000\\ 140, 000\\ 86, 000\\ 75, 000\\ 200, 000\end{array}$ |
| Total | 393, 042, 950 | 112, 848, 000 | 232, 311, 000 |

DULUTH STATION, MINNESOTA (S. P. WIRES, SUPERINTENDENT).

During the year a concrete sidewalk was constructed along two sides of the station grounds abutting the highway, and extensive improvements were made on the hatchery building, gravity flume, and steam plant. A large number of shade trees were also set out.

Of the 34,290 young steelhead trout on hand at the beginning of the year 30,000 survived and were distributed as fingerlings.

In August and September arrangements were made for the collection of lake-trout eggs at the usual points on Lake Superior, namely, at Grand Portage, Minn.; Port Arthur and Rossport, Ontario; Isle Royale, Manitou Island, Keystone, Ontonagon, and Marquette, Mich. The spawning season opened September 15 and closed October 31, resulting in a total collection of 15,771,000 eggs. Of these 3,771,000 green eggs were transferred to Cape Vincent, and 25,000 to the Pan-American Exposition, at Buffalo. Subsequent shipments of eyed eggs were also made to the number of 2,325,000.

The following table shows the number of eggs of various species received from other stations of the Commission and the disposition of same:

| Species. | Eggs re- ceivedfrom other stations. | Eggs collected. | Eggs shipped. | Fry distributed. | Fingerlings distributed. |
|------------|--|--------------------|------------------|--|-----------------------------|
| White-fish | | | 6, 121, 000 | $\begin{array}{c} 29,800,000\\ 7,150,000\\ 199,000\\ 92,230\\ 96,900\\ 32,000\\ \end{array}$ | 30,000 |

All eggs and fry were handled throughout the season with very light losses, and the fry resulting from the eggs received from other stations, and also the lake trout carried through the season, were all distributed in good condition in April, May, and June.

59

QUINCY STATION, ILLINOIS (S. P. BARTLETT, SUPERINTENDENT).

Throughout the navigable portion of the Illinois River, or about 250 miles, the banks in most places are low and any considerable rise of water overflows them, producing ponds and lakes varying in width from a few feet to 8 or 10 miles, in which the native fishes find desirable spawning-grounds. With the receding waters many of the adult fish and millions of fry become landlocked. Here they grow rapidly until, with the contraction of the water areas and the increasing demands for food, the waters become overstocked and the fish die in countless thousands from starvation or perish by the drying up of the ponds during the season of summer drought, when the temperature of both air and water become abnormally high. The work of the Quincy Station consists in the collection of them to the Illinois River, or their distribution to applicants throughout the country.

At the beginning of the year there were large numbers of fish in the ponds and the best of prospects for a good collection. The weather was hot, causing the moss to grow rapidly, but the evaporation was correspondingly great, so that little difficulty was experienced in cleaning out the moss to facilitate the use of small-meshed seines. The work of collecting continued good until July 22, when the water in the lakes and ponds, which were 10 to 12 inches deep, showed a temperature of 120 degrees, and the fish, large and small, came to the surface dead. Up to this time operations had been confined mostly to one lake, although the moss had been removed from others preparatory to working them. After July 22 operations were necessarily confined to the seining of the deeper ponds, but as the moss could not be removed the results were not so satisfactory as when collecting from the shallower waters. Operations extended over the entire navigable portion of the Illinois River. Great care was exercised in handling the fish on account of the usual high temperature of the water and the distance the fish must be carried from the river to the large towing live-boxes.

It is necessary to observe caution in rounding a haul to land the seine, because if the seine is hauled in rapidly to the shore the floundering of the larger fishes and the rolling of the moss will cause great injury to the fingerlings. Where possible the seine is brought together in deep water and a few feet at a time worked over, the fish being carefully placed in tubs and from them into the smaller liveboxes until rendy to haul over to the river, where they are placed in the large live towing-cars. They are then taken to the pumping station, placed in tubs until the temperature is gradually reduced, after which they are put in the retaining-troughs and held until the following day. Those showing signs of injury are removed and those selected for distribution are placed in the retaining-ponds. Early in the season it is difficult to induce the very small fry to take food, but as they grow older little trouble is experienced in that respect. Fish that have been kept a week or more in the retaining-ponds are in prime condition to bear transportation, but if sent to the distribution cars direct from the field where collected great mortality results.

The season of 1901 was an unusually disastrous one, all kinds of fishes perishing in the shallow overflowed ponds, owing to the high temperature, when in ordinary seasons they live and flounder around until all the water is gone and they are absolutely left on the bare mud. The total distributions of fish thus collected for the year were as follows: Black bass fingerlings, 50,900; adult black bass, 600; adult crappie, 2,170; adult warmouth bass, 100; adult sun-fish, 300; also 158 adult assorted fish.

At the close of the year the water in the river was $13\frac{1}{4}$ feet higher than the normal level, and too high throughout the month of June for the collecting of fish.

MANCHESTER STATION, IOWA (R. S. JOHNSON, SUPERINTENDENT).

During the year various improvements and repairs were made to the buildings, grounds, and waterways, the most important being the construction of three new ponds. These ponds were 15 feet wide at the top by 10 feet wide at the bottom, and 291 feet, 254 feet, and 140 feet in length, respectively.

Congress having made a special appropriation of \$5,000 therefor, a stern-wheel steamboat was constructed by Kahlke Brothers, of Rock Island, Ill., under the supervision of the superintendent. Other particulars in regard to this boat will be found elsewhere. On the morning of May 18 a violent rainstorm and cloud-burst broke over the station, flooding the southeast section of the reservation, destroying the wagon bridge and road from the main-entrance gate, and doing much other damage to the grounds. The upper spring reservoir was completely choked with mud, cutting off the water supply temporarily from the hatchery building and ponds. This resulted in the loss of about 75,000 of the 328,000 fry which were being held in the hatchery troughs. The property damage resulting from the flood was repaired by the station employees, assisted by temporary labor.

The output of fish and eggs during the year has been most gratifying, exceeding the work of all previous years.

The 60,000 brook-trout fry on hand at the opening of the year were reared to the fingerling stage, and in the fall 49,200 were distributed, 2,275 being held for brood stock. The loss incurred in rearing amounted to 8,525. The brood stock of brook trout, consisting of 1,209 two and three year old fish, were kept in one of the stock ponds in an apparently healthy condition until October, when they were transferred to the 80-foot ponds with plank sides, in readiness for the spawning season. Soon after the transfer was made the same peculiar disease which has attacked the brook trout at this station for the past

61

four years caused a heavy mortality. Efforts were made to check the disease, but without success, until the fish were again transferred to the earth ponds. Experiments conducted at this station prove that it is impossible to hold adult brook trout in the 80-foot wood-lined ponds, while there seems to be no difficulty in holding the same fish in the larger ponds with natural earth embankments.

From 257 ripe female brook trout 214,000 eggs were secured, or an average of 833 per fish. Of this lot of eggs 50,000 were shipped to applicants and 100,000 were hatched, but the fry were a very inferior lot and only 65,000 were distributed. The poor quality of the fry is attributed to the diseased condition of the parent fish. From the Spearfish and Leadville stations 250,000 brook-trout eggs were received, and 285,000 fry were hatched from the eggs received from all sources. Of these, 189,000 were distributed during the spring and 96,000 were held for fall distribution.

The 75,000 rainbow-trout fry on hand July 1 were carried until fall, when 69,000 were distributed and 3,000 held for brood stock. The spawning season of the rainbow trout extended from December 10 to March 21. The brood stock of rainbows consisted of 3,980 three and five year old fish, which were in excellent condition, having been held in the large stock ponds the greater part of the year. Out of this lot 1,296 ripe females yielded 1,247,400 eggs, or an average of 963 per fish. Of the total number of eggs secured 1,007,190, or 80 per cent, were eyed. Of this number 525,000 were shipped on assignment and 482,190 hatched. Of the fry thus obtained, 241,000 were distributed and 128,000 are being held for the fall distribution.

At the beginning of the year there were on hand 10 adult Loch Leven trout. During the month of November 8 ripe females produced 8,000 eggs. From this lot of eggs 6,000 fry were hatched, 3,500 of which are on hand at the close of the year.

There were also received from other stations in good condition 10,000 quinnat-salmon eggs, 10,000 landlocked-salmon eggs, 50,000 lake-trout eggs, 50,000 steelhead-trout eggs, and 100,000 grayling eggs, which produced strong, healthy fry, and these fry were distributed on assignments.

The food used for the brook and rainbow trout fry that were reared to fingerlings consisted of beef livers and mill shorts, boiled in varying proportions, according to the age of the fish. Live food collected from streams in the vicinity of the station was also used to some extent.

During the month of September the rock-bass ponds were drawn, and the young fish, numbering 14,450, were transferred to troughs in the hatchery, where they were held without loss until distributed. The stock of adult rock bass on hand at the beginning of the year numbered 235, but this number was increased by the addition of 45 adults collected from streams near the station. These fish were seen spawning in May, and the first fry were discovered on June 20. The indications are that the crop of young from this brood stock will be large.

The work of fitting up the Bellevue collecting station and overhauling the equipment preparatory to the season's work was begun May 27 and completed June 15. Active fishing operations commenced on July 1, under the direction of Mr. H. Crasser, assisted by the launch *Water Witch* and a temporary crew of six men. Fishing continued until October 12, an extra launch and an additional crew of five men being employed during the month of August. As a result of this work 100,976 black bass, 24,680 crappie, 16,820 cat-fish, 1,700 perch, 4,340 sun-fish, 600 bream, 305 pickerel, 75 pike perch, and 26 carp were collected in the lakes and bayous formed by the overflows of the Mississippi River. These fish were distributed by means of the U. S. Fish Commission cars to various applicants and planted in public waters throughout the United States.

While making the collections of young black bass and crappie large numbers of the more common varieties of fish were seined from the warm shallow lakes and liberated in the Mississippi River between Dubuque, Iowa, and Savanna, Ill. On account of the large number of fish handled and the necessity of transferring them quickly, it was not practicable to count them, but it is estimated that there were transferred in this way 5,000 black bass, 700,000 crappie, 600,000 sunfish, 500 pickerel, 43,500 cat-fish, 35,000 carp, 500 pike, and 200,000 buffalo, a total of 1,584,500. This is regarded as a conservative estimate, and it is believed to fall short of the actual number transferred.

SAN MARCOS STATION, TEXAS (J. L. LEARY, SUPERINTENDENT).

An appropriation of \$8,000 for enlarging and improving the station having been secured, two tracts of land (one cutting into the southwest corner of the grounds and the other extending about 300 feet along the river front) were purchased at an expenditure of \$3,200. This property rounds out and adds greatly to the appearance of the station and makes it possible to conduct operations on a much larger scale.

Four ponds, covering about 3 acres, were constructed at an expense of \$2,252, and a pumping plant of 1,000 gallons capacity was installed. The latter consists of a 10-horsepower gasoline engine of the Springfield type and a No. 6 centrifugal pump, with 6-inch suction and

63

8-inch discharge. The entire cost of installing it, including the construction of a substantial engine-house and pump-pit, amounted to \$1,125. While in operation the pump requires very little attention, and the cost of running it for a period of 8 hours is only \$1.40. The plant has already proved invaluable, the station having been entirely dependent upon it at one period during the severe drought which has continued almost without intermission for two years. A building on one of the acquired pieces of land was removed to the southwest end of the reservation and fitted up as a residence for the foreman. Wire fencing was constructed around the orchard and superintendent's dwelling and a large number of shade trees set out.

The four new breeding-ponds for the large-mouthed black bass necessitated the collection of additional brood fish from the San Marcos River, the stock being increased during the winter to 360, not including 90 eighteen-months-old fish which have been reared under domestication. The spawning season of the black bass began over a week later than in past seasons, not a nest being observed until February 18, whereas the first nesting has usually occurred from February 8 to 10. The first fry made their appearance on March 10, but the weather at this time was very cold, the water temperature being 58° , and nearly all of this school died. During the year 103,580 large-mouthed black bass were transferred from the breeding-ponds and 81,260 distributed.

The 70 adult crappie on hand were placed in a breeding-pond prepared for them, together with the necessary number of carp for keeping the water roily. During the year 6,490 were removed from the ponds and 4,455 distributed. This fish is considered as invaluable for the muddy lakes and streams of Texas, being a prolific breeder, rapid in growth, and a fine table fish. Its propagation has hardly advanced beyond the experimental stage, however. The breeding season opens in March, continues well into the summer, and young fish have frequently been observed spawning during the fall months.

Early in the spring 38 bream were placed in one of the breedingponds and commenced nesting late in April. The spawning season of this species extends through the summer into early fall. During the year 3,410 young fish were taken from the pond and 2,830 distributed.

The rock bass is the most desirable pond fish cultivated at the station for ponds of an acre or less in area. These fish begin to spawn early in March and the spawning season continues until July. During the year 9,360 were transferred from the ponds and 4,555 distributed. The brood stock on hand at the close of the year consisted of 5 adult fish brought from Neosho in the winter of 1898 and 25 two-year-old fish. These were placed in two ponds previous to the spawning season and from them a good crop of young fish is expected for distribution the coming season.

Of the 10 calico bass received from Neosho in the winter of 1898, 6

remain, and these, with 17 two-year-old fish, were placed in two ponds previous to the spawning season, which began March 10. The product from this brood stock during the year amounted to 1,450 young fish. At the close of the year the ponds had not been drawn, but the young fish seen in them appeared to be about one-third larger than rock bass of the same age.

The question of fish food is an important one in the conduct of a pond station. As most of the streams in the vicinity from which supplies of food have been obtained in previous years had dried up, it was difficult to secure natural food in abundance and cannibalism among the young was much more prevalent as a result. Carp and mud shad have been propagated for a supply of fish food. The carp are placed in the ponds with the bass, where the young make excellent food for the fry. River shrimp have been planted in the ponds in large numbers, but as they have no protection are soon devoured. They make very excellent food for all kinds of fry in the ponds. Crawfish, also a valuable food supply, have been scarcer than for the past four years. Bullfrogs breed in the ponds, but were not so plentiful as in former seasons. Their young make fine food for the adult bass.

Blind cave salamanders and shrimp continued to come up with the waters of the artesian well.

It becomes necessary in the protection of the fish to kill many wild ducks, other water fowl, and snakes, as they are very destructive to the young fish.

With very few exceptions the railroads of the State have given free transportation for messengers with cans of fish and messengers returning with empty cans, thus contributing very largely to the success of the station.

NEOSHO STATION, MISSOURI (H. D. DEAN, SUPERINTENDENT).

The construction work begun last year was continued throughout the year. The hatchery was reconstructed and changed from a low one-story to a two-story building, the office was enlarged, and a hotwater furnace was installed for heating the building. The hatchingroom is now 28 by 36 feet, with space for 20 hatching-troughs and a capacity for 1,000,000 trout eggs. A room of the same size on the second floor is used for storage and workshop. Some necessary repairs were made on the residence and a new pond, 12,000 square feet in area, was constructed. Two of the old ponds were enlarged, deepened, and repiled with 14-inch cypress, and a drainage sewer 800 feet in length was constructed. Over 200 feet of retaining wall and gutter were constructed to protect the embankments on the north side of the station property, a cement concrete walk was built from the hatchery to connect with the walk on the south side of the driveway, and considerable grading was done around the ponds and grounds. This construction interfered somewhat with fish-cultural work, as some of the ponds were undergoing repairs during the spawning season.

Of the 51,500 young rainbow trout on hand at the beginning of the year 44,088 were distributed in the fall and 2,000 were held for rearing. The adult rainbow trout were placed in the rearing-ponds early in December, and from them 487,011 eyed eggs were obtained. Of these, 91,296 eyed eggs were the product of 376 two-year-old female trout, being 63½ per cent of the total number of green eggs taken from these young fish, and a much better percentage than usual for fish of this age. Of the eggs thus obtained 304,415 were shipped on assignment, 25,000 were distributed as fry when 3 months old, and 77,000 remained on hand at the close of the year.

Shipments of eggs from other stations to be hatched and the product reared for the aquarium at the Louisiana Purchase Exposition were received as follows: Quinnat salmon eggs, 10,000, which were hatched, and the product at the close of the year amounted to 6,900 young fish; landlocked salmon, 5,000, which nearly all died in hatching, only about 200 remaining at the close of the year; steelhead, 10,000, which hatched well and grew nicely, the product on hand at the close of the year being 6,400; grayling, 25,000, large numbers of which died in process of hatching, though 8,000 remained at the close of the year and were in fine condition.

In addition to the propagation of the *Salmonidæ* above referred to, the various fishes propagated in ponds were handled at the station, and while the work during the year was not entirely successful, 32,965 yearlings were distributed, as follows: 18,400 rock bass, 3,251 strawberry bass, 9,514 black bass, and 1,800 sun-fish.

LEADVILLE STATION, COLORADO (E. A. TULIAN, SUPERINTENDENT).

At the beginning of the year there were on hand 260,800 brook-trout fingerlings, of which 30,000 were planted during the month of July, 9,000 in August, 53,000 in September, and 35,500 in October, the losses during this time amounting to about 51 per cent.

The usual arrangements were made for the collection of brook-trout eggs in the fall from lakes belonging to private individuals, and the results of the work are embodied in the following statement:

| Source of supply. | Spawning season. | Eggs col- lected. | Percent- age of loss. | Fry hatched. | Eggs shipped. |
|---|--|---|--|--|---|
| Station brood fish Uneva Lake Smith's ponds | Oct. 3 to Dec. 6 Oct. 23 to Nov. 27 Oct. 21 to Dec. 5 Nov. 1 to Nov. 28 Oct. 19 to Nov. 23 Oct. 14 to Nov. 26 Oct. 28 to Dec. 7 Oct. 28 to Nov. 2 | $\begin{array}{c} 235,300\\ 261,700\\ 197,300\\ 1,303,400\\ 1,013,700\\ 569,300\\ 225,300\\ 443,800\end{array}$ | $\begin{array}{c} 81\\ 13.5\\ 12.3\\ 15.9\\ 21.9\\ 22.8\\ 19.2\\ 9\end{array}$ | $\begin{array}{c} 226,500\\ 128,300\\ 941,200\\ 680,800\\ 257,100\\ 182,000\\ 378,700 \end{array}$ | 162, 540 153, 400 111, 700 183, 200 25, 000 |
| Total | | 4, 249, 800 | 20.7 | 2, 797, 600 | 635, 840 |

Reference was made in last year's report to the improvement in the percentage of eggs which produced fry owing to the fact that the practice of stripping young fish had been discontinued. This year the F. G. 1902—5

65

lines were drawn somewhat closer, and when in doubt as to whether a fish was spawning for the first time or not it was put aside without taking the eggs. As a result the loss on each lot of eggs was from 20 to 50 per cent less than on lots taken from the same places last year. Undoubtedly a very much larger percentage of eggs would produce strong, healthy fry were it possible to secure the eggs from wild fish without confining them for a considerable period, during which time it is necessary to handle them over and over again; but the conditions under which the collection of eggs is made in Colorado are such that there is no other practicable way, and most of the wild fish must be caught early in the season and penned until ripe.

After the eggs were eyed 675,000 were shipped on assignments, and in every instance the assignments reached their destination in good condition. One case of 25,000 eggs was sent to Tokyo, Japan, with a loss of 12 per cent en route and a subsequent loss of 2,000 during the period of incubation.

Although the total number of eggs taken was somewhat less than the number taken last year, the percentage of fry hatched was greater than last year, and the number of fish available for distribution proportionally greater. On May 20, when all the brook-trout eggs had been hatched, there were on hand 2,664,440 fry, of which 1,087,115 belonged to the Commission and 1,577,325 to the parties who had furnished the eggs. Between this time and the end of the fiscal year there was a loss of $6\frac{1}{2}$ per cent of the fry belonging to the Commission; 745,000 were planted, and there remained on hand 271,000.

Of the 68 adult Loch Leven trout on hand at the beginning of the year 33 died, and during the months of November and December 30,600 eggs were obtained from the remainder, from which 18,500 fry were hatched; 3,000 of the fry were distributed in June, and the balance on hand at the close of the year amounted to 2,450. The eggs were of inferior quality, as the parent fish were past their prime. The introduction of the Loch Leven trout has not proved very successful, and its propagation will be discontinued.

Of 1,525 two-year-old rainbow trout on hand July 1, 1901, 675 died and 200 were shipped on assignment, leaving 650 on hand at the close of the year. There were also 6,790 fry in the rearing-ponds, of which 5,000 were shipped and 1,790 died. During the months of February and March, 109,800 eggs were collected from Ridgway's ponds, 50,000 were acquired from the station at Manchester, Iowa, and 100,000 were purchased from J. P. Morrill, Verdi, Nev. These eggs produced 227,075 fry, of which 160,000 were distributed during the month of June, 41,550 were returned to the owner of the ponds, the balance being lost.

In February 25,000 lake-trout eggs were received from the Duluth Station, and hatched with a loss of 900. The fry from these eggs did not do well, 16,600 of the young dying before the close of the year.

Out of 76 three-year-old grayling in stock at the beginning of the

year, only 15 remained at the close of the year. The domestication of the grayling has not proved a success, the few fish on hand having been carried for experimental purposes. On the 21st of May 131,200 eyed grayling eggs were received from the Bozeman Station, 120,000 of which hatched, and during the month of June a distribution of 100,000 fry was made in Colorado waters.

On the 23d of May 35,000 steelhead eggs were received from the collecting station at Medford, Ore., from which 34,090 fry were hatched, and 33,900 healthy and rapidly growing fish remained on hand at the end of the year.

On the 26th of February 10,000 landlocked-salmon eggs were received from Craig Brook Station, from which 9,800 fry hatched, and at the close of the year 9,450 remained on hand.

At the beginning of the year there were on the hatching-trays 1,317,800 black-spotted trout eggs, to which may be added the collections during the month of July, amounting to 863,900. Of the 2,181,700 collected, 175,000 eyed eggs were shipped elsewhere and the balance hatched, with a loss of 17.6 per cent. The distribution of these fish was made during the fall, when 847,000 were planted for the Commission and 560,000 for the owner of Grand Mesa Lakes, the point of collection. During the month of June, 3,016,700 eggs were collected at Grand Mesa Lakes, and the loss to June 30 was 106,000, or $3\frac{1}{2}$ per cent, leaving on hand at the close of the year 2,910,700.

For two months during August. September, and October the superintendent was detailed to collect statistics and methods of the fisheries in Utah and Colorado. During this time the station was in charge of W. K. Hancock, fish-culturist.

No material improvements were made at the station during the year in the way of new constructions, although, so far as the funds would permit, the property was kept in good repair. A new tin roof was laid on the kitchen, coal-shed, and storeroom of the messhouse. A small room was built in the workshop, with an inside lining of tin, in which to store seines and nets. The grounds were inclosed by a Page woven-wire fence along the south side and the greater part of the west side, and the balance of the west side was inclosed with a barbedwire fence.

The stock of fish on hand at the close of the year is shown by the following table:

| | Calen | dar year ii | n which fis | sh were ha | tched. |
|---|--------------------------|-------------|-------------|------------|--------|
| Species. | 1902. | 1901. | 1900. | 1899. | 1898. |
| Brook trout. Loch Leven trout Rainbow trout | 2,450 | 1,000 | 650 | | |
| Grayling Lake trout. Landlocked salmon Steelhead trout | 7,500 9,450 33,900 | | | | |
| Black-spotted trout | 324, 300 | 1,000 | 650 | | |

67

SPEARFISH STATION, SOUTH DAKOTA (D. C. BOOTH, SUPERINTENDENT).

During the year the station grounds were materially improved by the construction of a stone bulkhead 82 feet long, 4 feet wide, and 6 feet high across the canyon outlet, and a channel, in places 6 feet deep and 8 feet wide, was cut through the upper grounds to connect with the storm channel constructed last year. Although still incomplete. the channel is sufficiently large to care for sudden accumulations of water from the canyon during ordinary rains, and has during the past vear carried off the surface water, thus preventing the pollution of the water supply to the hatchery, and as a consequence the percentage of eggs hatched was higher than heretofore. During the summer much trouble was experienced owing to a decrease in the volume of. the spring-water supply, which is the main source of supply for the hatchery and ponds. From time to time, as the regular force could be spared from the fish-cultural work, and with some temporary assistance, the sources of the springs rising on the reservation in the canvon were developed with gratifying results, and it is believed that by continuing this work the present volume of water can be doubled. A driveway was laid to grade through the station grounds, and, together with other completed portions of the grounds, sown to grass. Shrubs of various kinds were planted, and 47 shade trees were set out.

The fish on hand at the beginning of the year in course of rearing were distributed as fingerlings and yearlings during the summer and fall, with the exception of a lot of rainbows which were retained to rear for a brood stock. The output amounted to 73,500 brook trout, 5,000 Loch Leven trout, and 10,000 rainbow trout.

On the 1st of July there were on hand 1,200,000 black-spotted trout eggs at the collecting station in the Yellowstone Park. As soon as the eggs were properly eyed they were packed in refrigerator cases in lots of about 250,000 each and transported 74 miles by wagon to Cinnabar, Mont., thence by rail to Spearfish, where they were hatched, and during the fall and winter 382,000 fry were distributed to applicants or planted in the waters of the Black Hills. The substation in the Yellowstone National Park was again opened in the early part of June, 5 men being detailed for the collection of eggs at that point. At the close of the year there were in the troughs 1,934,000 eggs.

During the fall the brood stock of brook trout at the station was largely increased by seining the creeks in the vicinity of the station, and resulted in a larger collection of eggs from this source than in previous years. During the early fall arrangements were made with persons in the vicinity of the station who had a supply of stock fish to collect and hatch the eggs at the station on shares. The first eggs were taken October 26 and the spawning season continued until January 14, when the last eggs were taken from the brood fish at the station. The total number of brook-trout eggs collected from all sources amounted to 1,065,000, of which 112,000 green eggs were given to the owners of stock fish, 113,477 were lost during incubation, 355,000 eyed eggs were shipped to other stations, and the balance produced 496,523 fry. Of the fry, 50,023 were lost in the hatchery, 77,500 were given to the owners of stock fish, 269,000 were distributed as fry during May and June, and at the close of the year 100,000 fry remained on hand in course of rearing for distribution as fingerlings and yearlings.

The Loch Leven trout at the station began spawning October 23 and finished November 29, when 16,375 eggs had been collected. The product of these eggs amounted to 14,000 fry, which were distributed during May and June.

On February 10th 50,000 rainbow-trout eggs were received from the Manchester Station in good condition. The 41,500 fry from these eggs were distributed to various applicants and planted in streams on the Rosebud Reservation and in Spearfish Creek.

Between March 20th and May 31st 3,670 adult rainbow trout were seined in the Laramie River and Sodergreen Lake, about 20 miles south of Laramie City, Wyo. Only 183, or 5 per cent, of these fish produced any eggs, the total collection amounting to 170,000, which, after being eyed at the hatchery of the Wyoming Fish Commission, were divided equally between the Laramie State hatchery and the Spearfish Station, the latter receiving 75,000, the product of which at the close of the year amounted to 60,000 fry.

At the close of the year the stock of fish on hand was as follows:

| | | Calendar year in which fish were hatched. | | | | | | |
|--|-----------|---|-------|----------------|-------|--------------|--|--|
| Species. | Eggs. | 1902. | 1901. | 1900. | 1899. | 1898. | | |
| Brook trout Loch Leven trout | | 100,000 | | $690 \\ 2,239$ | | 1,000 104 | | |
| Rainbow trout. Black-spotted trout. | | 60,000 | 5,000 | | 390 | 54 | | |
| Total | 1,934,000 | 160,000 | 5,000 | 2,929 | 390 | 1,158 | | |

BOZEMAN STATION, MONTANA (JAMES A. HENSHALL, SUPERINTENDENT).

The work at this station was confined to the propagation of brook trout, black-spotted trout, steelhead trout, rainbow trout, Montana gravling, and the collection of eggs at auxiliary stations.

The work at the auxiliary station for the collection of black-spotted trout eggs at Henry Lake, Idaho, was in charge of Mr. W. F. Jarvis, who took the first eggs April 4 and the last May 24. From 700 females there were obtained 871,500 eggs, an average of 1,200 per fish. Ripe males were very scarce during the season, and the loss of nearly a half million eggs is to be attributed to this cause. Besides the eggs transferred to the Bozeman Station, 235,000 were shipped to other stations and applicants, one assignment going to Belgium. The temperature of the water in the hatchery during the season varied from 40° to 54° F., the water in the spring pool being much influenced by the air temperature. The auxiliary station at Red Rock Lake, Montana, for the collection of grayling eggs, was in charge of Mr. G. H. Tolbert. The first eggs were taken on April 21 and the last on May 31. Ripe fish of both sexes were very plentiful, and the number of eggs collected could have been greatly augmented had the station been equipped with more hatching-jars, in which the eggs are eyed. The collection amounted to 4,463,000 eggs, which were eyed in 21 jars. In addition to the eggs shipped to Bozeman Station there were shipped to other stations and applicants 1,455,000. More than 2,000,000 were hatched and the fry planted in streams contiguous to the substation. The temperature of the water in the hatchery varied from 49° to 53° during the season.

Mr. Tolbert reports that the streams are swarming with yearling grayling from the plant of last season, which indicates that grayling fry thrive well when planted early.

The number of eggs collected at Bozeman Station and received from the auxiliary stations during the year numbered 1,429,000, as follows: Black-spotted trout, 615,000; steelhead trout, 83,000; rainbow trout, 2,000; brook trout, 129,000; grayling, 600,000.

The number of eggs received from other stations during the year was 282,700, as follows: Brook trout, 197,000; rainbow trout, 47,000; lake trout, 38,700.

During the year 2,946,000 fry and fingerlings were distributed in Montana, Idaho, Oregon, and Washington, as follows: Black-spotted trout, 262,000; brook trout, 24,000; steelhead trout, 10,000; grayling, 2,650,000.

The water in the hatchery at the Bozeman Station is uniformly 45° during the winter and 44° during the summer months, when the snow is melting in the mountains. During the past fall the wall of the warm spring was raised and extended, giving a fall of 18 inches to the creek-water ditch. As the water of this spring is 77° during the entire year, it keeps the water in the ditch from freezing in the winter, thus insuring a constant supply of creek water the year round. After the fry are hatched in the spring water it is shut off and the creek water is utilized for the fry. As it never rises above 65° in summer, contains a great deal of natural food, is more highly aerated, and is clear and pure after the spring rise, or from the middle of June, it is preferable to the spring water for the fry.

The different species of trout sent out from the station have done exceedingly well wherever planted. The steelhead trout and brook trout have shown a growth quite remarkable, in some instances weighing 3 pounds at little more than 2 years of age where the supply of natural food was abundant. There was sent to the station a blackspotted trout 24 years old that weighed 3 pounds dressed. It had been placed, with others of the same hatching, in a carp pond near Toston, Mont., which may go to show the value of young carp as trout food. During the past year there has been no evidence of disease among the fry at this station. A few of the black-spotted male trout were injured by fighting and some by jumping against the supply pipes during the spawning season, resulting eventually in their loss. The same causes also account for a slight loss of steelhead trout; otherwise all stock fish have done very well. They are fed on mush made of 1 part beef or sheep liver and 3 parts of mill shorts from which the bran has been taken. This food is well assimilated and taken with avidity.

At the close of the fiscal year the following fish were on hand:

| Species. | Calendar year in which fish were hatched. | | | | | |
|---|---|-------------|-------|-------|--|--|
| | 1902. | 1899. | 1898. | 1897. | | |
| Brook trout Black-spotted trout Steehead trout Rainbow trout Lake trout Grayling | $\begin{array}{r} 225,000\\ 21,000\\ 37,000\\ 18,000\\ 25,000\end{array}$ | 1,574 40 | 1,580 | 268 | | |
| Total | 575,000 | 1,614 | 4,184 | 263 | | |

BAIRD STATION, CALIFORNIA (G. H. LAMBSON, SUPERINTENDENT).

The work at this station is confined to the propagation of the quinnat salmon. At the beginning of the year the various racks were in place and some salmon had collected in the fishing pool; the current wheel used to supply the hatchery with water was in running order, and all hatching equipment had been cleaned and painted. During the month of July the spawning-house, fish-pens, whim, and seine reel were made ready for active operations. Twice during the season the current wheel broke down. The first time it was repaired by the station employees, but the second time it was necessary to replace the countershaft. On each occurrence the steam pump was operated during the time the current wheel was out of service and thus kept the hatchery supplied with water.

Fishing began on August 16, when 4 ripe females were obtained. The following day 37,200 eggs were taken from 7 females. Fishing and spawning operations continued until September 25, when the season's operations with the summer run of salmon closed. The fall run of fish began October 25, with a catch of 8 ripe females, and the following day 66,400 eggs were obtained from 10 females. Fishing and spawning operations continued until November 25.

From the summer run 7,375,520 eggs were taken from 1,203 females, or an average of 6,130 per fish. The fall run yielded 1,557,770 eggs from 233 females, or an average of 6,690 per fish. Of the total collections, amounting to 8,933,290 eggs, 5,706,410 were shipped to the California Fish Commission at its Sisson and Eel River stations, 30,000 were shipped to the Pan-American Exposition at Buffalo, N. Y., and 10,000 to each of the stations of the Commission at Neosho, Mo., and Manchester, Iowa. From the balance of the eggs collected 2,115,560 healthy fry were planted in the McCloud River. The fry from the summer run, S11,900 in number, were planted just as the umbilical sac was absorbed, all the trough room being required for the eggs from the fall run. The fry from the fall-run fish were held in the troughs until April and when planted averaged about $2\frac{1}{2}$ inches in length. A lot of 100,000 fry from the fall run were reared in an earthen pond, and at the end of the season, when the plants were made, averaged slightly larger than those retained in the hatching-troughs.

The method of stripping and fertilizing the eggs was the same process used during the past five years, with the exception that after the regular spawning all females were killed and opened to secure the balance of the eggs in them which could not be extruded in the regular way. These eggs were washed in a normal salt solution and then fertilized. As a result about 12 per cent more eggs were secured than if the usual methods had been pursued.

The food for rearing the fry consisted of liver, liver and mush mixed, and canned salmon. Heretofore much difficulty has been experienced from feeding the canned salmon, as it dissolved in the water so quickly that the fish could not find particles large enough to eat and the water became so milky as to obscure the fish from view. It also fouled the troughs, covering the sides and bottom with a greasy scum. and collected on the gills of the young fish. During the past season these difficulties were obviated by submitting the canned salmon to pressure in a press made for the purpose, somewhat similar to a hand cider-press. The moisture was pressed from the salmon until it could be squeezed in the hand like damp earth, and in this condition it held together well in the water and did not foul the troughs much more than liver or liver and mush. For experimental purposes eight troughs of fry of about the same age were set aside, four troughs being fed on nothing but canned salmon and the other four on liver at first and then a mush of liver and shorts. When the fry were planted there was no apparent difference in the size or condition of the two lots, the fry fed on the canned salmon appearing as strong and healthy as any in the hatchery. The first cost of the canned salmon is about the same as that of the liver and mush, but it is always available when once canned and the labor necessary to secure and prepare the liver and mush is avoided.

On October 5 the foreman's cottage was reported on fire, and although all the employees were at hand ready to do what was possible to extinguish the flames the building was entirely consumed within half an hour, the foreman losing nearly all of his personal effects.

During the summer there were many fires on the hills and around the reservation. In September the fires entered the southern part of the reservation, endangering the woods back of the superintendent's residence. The spread of the flames was prevented by back-firing. On January 16 Colchoolooloo, one of the oldest and most influential Indians on the reservation, died in his hut. He was a consistent friend of the white people, and in former years saved the superintendent from being killed by the Indians. His influence was always exerted toward keeping his people sober and industrious. He was buried on the reservation upon a hill, where he had selected a site for his grave.

From October 18 to December 18 the superintendent was absent from the station, detailed to act as messenger in the transportation of a shipment of salmon eggs from San Francisco to New Zealand.

On April 24 a quinnat salmon was noticed spawning in the river opposite the hatchery. It had about finished spawning, only 10 or 15 eggs being secured. It is not known whether this fish was a straggler from the fall and winter run or an early comer in the spring run.

BATTLE CREEK SUBSTATION, CALIFORNIA (OPERATED FROM BAIRD STATION).

In order to determine the extent of the spring and summer run of salmon the racks had been put in place during the month of April. A large run of fish came into the seining-pool during the late spring and early summer, but owing to the extreme heat they died without ripening. The experiment proved that there is a large summer run of fish in the creek, but it also proves that it is impossible to secure eggs from this run at the Battle Creek Station. A new stone-ballasted crib pier was constructed at the mouth of the ditch and the water turned in by the aid of a wing dam. All hatching-troughs and equipment were cleaned and asphalted and the general repairs about the station completed.

The first fishing occurred October 22, when 13 ripe females were caught, and the following day from 41 ripe fish 238,700 eggs were taken. Fishing and spawning operations continued until December 1, when portions of the racks were washed out and the balance of the salmon on hand escaped. The total number of eggs collected amounted to 10,059,000, of which 705,000 were lost during incubation, and 9,354,000 were shipped to the Sisson Station of the California Fish Commission. The fry resulting from the eggs shipped to the Sisson Station were all planted in the Sacramento River and tributaries.

The ordinary method of stripping the fish and fertilizing the eggs was pursued the same as at Baird, and after each stripping all the female fish were cut open to secure the balance of the eggs in them. The eggs were washed in a normal salt solution and then fertilized. By this method 1,512,630 eggs were obtained, or 15 per cent of the total take. The entire loss of eggs from all causes was 0.07 per cent. The method of handling the eggs was different from that followed at the Baird and Mill Creek stations in that after the second day they were left undisturbed until they emerged from the tender period or when the blastopore was fully closed, while at Baird and Mill Creek the eggs were picked daily. The results from this experiment were not

definite or satisfactory, as the eggs proved to be better than those at Baird Station and not as good as those at the Mill Creek Station.

On November 28 a very heavy rainstorm occurred and by night the creek was raised over 7 feet. A large amount of drift came downstream and lodged against the racks and the entire force were engaged in removing it in order to save the racks. This work proved unavailing, and just as the men were ordered to desist C. H. Storrs, a temporary laborer, was caught by a log and killed. The coroner's jury returned a verdict of accidental death and exonerated the Commission from all blame. The work of clearing the racks in times of freshet is hazardous, but this is the first fatal accident that has occurred at any of the California stations, although there have been several narrow escapes.

Toward the close of the year racks were put across the mouth of the creek to turn the salmon into the river and force them up the McCloud, where they can be retained until ripe. The results of this experiment can not be foretold at the close of the year.

MILL CREEK SUBSTATION, CALIFORNIA (OPERATED FROM BAIRD STATION).

This is a new station situated on Mill Creek, a stream which has its source in the foothills of the Sierra Mountains in the northeastern part of Tehama County, and emptying into the Sacramento River from the east about a mile above the town of Tehama.

Investigations made toward the close of the previous year demonstrated that there was a large run of salmon in this creek, and in order to take and eye the eggs a hatching-shed 80 feet long by 40 feet wide, with 10-foot studding and open on all four sides, was erected. A water supply of 1,000 gallons per minute was obtained by tapping a mill-race and thence conducting the water to a settling tank in the hatchery through 78 rods of ditch and 57 rods of flume. The water thus used is returned to the mill-race, and is furnished free of charge. In the hatching-shed 80 troughs, $15\frac{1}{2}$ feet long, $11\frac{1}{2}$ inches wide inside measure, and $6\frac{3}{4}$ inches deep, were erected. When fully equipped the hatchery will have a capacity of 10,000,000 eggs. A small tool-house and storehouse were also constructed.

The site having been selected before the close of the last year, the racks were all in place at the beginning of the year. The upper rack, 75 feet long, is composed of three stone-ballasted piers, upon which rest three double stringers. The racks are 14 in number, made in sections $5\frac{1}{3}$ feet wide and 9 feet deep, with a space of $2\frac{1}{4}$ inches between the slats. These racks rest upon stringers at the top and on the mud sill, which is placed across the stream at the bottom. The lower rack is constructed in the same way except that it is 85 feet long and has three V-shaped openings or traps, the angle of the V being upstream.

The salmon of the summer run which were intercepted by the racks all died before becoming ripe enough to spawn, death being due to the extremely warm weather. The fall run was not large because the creek was very low, while at the same time the Sacramento was several feet above the low-water mark. The run began during the last week in October, and fishing commenced October 30 and continued at intervals until the close of the season on December 2, when 2,561,000 eggs had been secured from 451 female salmon. The loss during incubation was 141,000 eggs, or 0.055 per cent. All of the eggs were shipped to the California Fish Commission—1,000,000 to the Price Creek hatchery and the remainder to Sisson. The method of fertilization was the same as at Baird and Battle Creek.

As it has been found impossible to secure eggs from the summer run of fish at the Mill Creek Station, during the spring temporary racks were constructed across the mouth of the creek in order to turn the salmon back into the Sacramento River with the hopes that a large proportion of them would continue up the river and on to Baird Station, where the water is colder and the eggs can be taken. A large run of salmon passed up the river during May and June, and the fish were continually fighting the racks, but all were compelled to return to the river.

CLACKAMAS STATION, OREGON (J. N. WISNER, IN CHARGE).

Mr. E. N. Carter, who was in charge of the station for the first six months of the year, having been relieved, Mr. J. N. Wisner, field superintendent, was placed in charge for the balance of the year, and on February 15 Mr. Carter was transferred to St. Johnsbury, Vt.

The initial work of the year consisted in the care of the few fish on hand at the end of June, cleaning up of the station buildings, and the construction of a fence around the premises. On July 24 the construction of the rack across the Clackamas River a short distance below the station was undertaken and the work completed early in August. Owing to the fact that about 2,000 cords of wood were being floated down the river, it was necessary to construct a boom above the rack on either side of the river to a point in the rack where a gate was made to allow of its passage. This gate was constructed of 1-inch boards, 4 inches wide, placed with their edges to the current and hinged to an iron rod below the surface. After the rack had been completed the employees were set to work on the bed of the river, which was cleared of bowlders and snags and put in condition for fishing. Live pens were made for retaining the salmon, and other work preparatory to the fishing season was done.

Fishing with gill nets began on the evening of September 22, and on the following morning 43,000 eggs were taken from eight ripe females. The run of fish gradually increased until October 15, when 194 were taken, 94 being females, and from these 412,000 eggs were secured, making the largest single day's work of the season. By November 8th 10,018,000 eggs had been collected, and as the capacity of the station was taxed to its utmost it was necessary to discontinue collections. The rack was at once opened, that the remaining salmon might have free passage to the upper waters for spawning. A large portion of the rack was saved and stored for future use. The total loss of eggs was 1,347,850, or about 13 per cent of the entire collection.

The females were spawned in the same manner as that practiced throughout the Columbia River territory, except that after the greater portion of the eggs had been removed an incision was made in the belly of the fish, the eggs shaken free from the enfolding sac, and then pressed from the vent. In this manner the egg take was added to materially, but the eggs thus taken were not of the best quality. On November 10, after a period of incubation of fifty days, the eggs began hatching, and owing to lack of space it became necessary to plant the greater portion of the fry as soon as they hatched.

With the view to affording them as much protection as possible, a series of dams was thrown across the small branch leading from the hatchery to the Clackamas, it having first been cleaned, and into the small ponds thus made throughout its length the fry were liberated. By January 1 over 6,000,000 fry had been planted, and the balance, 2,412,000, were held in troughs and outside tanks to be reared for a time upon artificial food. In each tank 36,000 fry were placed and in each trough 18,000, but on January 9 it was necessary to thin them out by distribution, leaving 15,000 in each tank and 5,000 in each trough. The fry loss for the year amounted to 128,866, or 1.48 per cent of those hatched.

During September and October 220,000 eyed quinnat-salmon eggs were received from the Oregon Fish Commission. Of these, 10,000 were loaned to the Portland Carnival in connection with its exhibit and 175,472 fry hatched from the remainder were planted in the Clackamas River.

In February 900,000 white-fish eggs were received from the Northville, Mich., Station, and after being successfully hatched the resulting fry, numbering 750,000, were planted in Lake Sequalitchew, Washington.

In July and August the rainbow and brook-trout fry carried over from the previous year were planted under the direction of the Oregon Fish and Game Association.

In one of the rearing-tanks 20 quinnat salmon had been held until 18 months old, and on June 26, 1902, copper tags were placed upon them and they were liberated in the Clackamas River.

At the request of the committee in charge a model salmon hatchinghouse was installed as an exhibit at a carnival held in Portland, Oreg. All the equipment used was made one-third the regular size and was furnished by the committee. The Commission loaned cans, packing, and such other articles as could be spared. The installation of this exhibit was under the direction of the superintendent until completed, and it proved to be very interesting and instructive to the visitors at the carnival.

On the 25th of February 100,000 brook-trout eggs were received from the Leadville, Colo., Station, and early in March another shipment of the same number came from the same place. These eggs were received in fine condition, hatched well, and the resulting fry, after being fed for a short time, were planted in waters of Oregon and Washington.

On March 16 a shipment of lake-trout eggs was received from the Duluth, Minn., Station in good condition, and began hatching March 23. The loss of fry was heavy, but was due to the fact that one of the screens elogged up, forming a current, which destroyed a large number. The fry were planted in Lake Sequalitchew, Pierce County, Wash., and in waters in Oregon.

During May 10,000 cut-throat trout eggs were received from Verdi, Nev., and the fry hatched from them were planted in waters in Clackamas County, Oreg.

On May 23 the first shipment of steelhead eggs, numbering 40,000, was received from the Rogue River Station, and on June 3 a second lot of 30,000 arrived in good condition. The eggs hatched well, and at the close of the year the fry were doing nicely.

The food used consisted at first of pure liver and later of liver mixed with Germea. This was prepared by stirring the Germea into very hot water, to which a little salt had been added, and then grinding the mixture with the liver to thoroughly combine the ingredients.

ROGUE RIVER STATION, OREGON.

This station was operated as a substation of Clackamas. The construction of the rack across the river to stop the ascent of the quinnat salmon was commenced on July 5 and completed within five days, the expense of building it being much less than usual, as most of the material in the last year's rack was again utilized. For the remainder of the month and during the early part of August the time of the men was taken up in general repairs to the equipment preparatory to the opening of the salmon work, and in making various improvements, the most important being the construction of a large water-wheel capable of lifting 100 gallons of water per minute, and the erection of 28 hatching-troughs. A strong boom was also anchored in the river above the wheel to protect it from driftwood, and a large supply tank was built. The money for making these improvements was furnished by Hon. R. D. Hume.

The fishing season opened August 20, when 2 ripe females were stripped, and from that time to the end of October eggs were obtained daily, the total collections aggregating 5,601,000. The entire number of ripe females stripped was 1,515, and the largest take of eggs was on October 21, when 385,000 were secured. The last eggs were taken on November 5, and on the 26th of that month one-third of the season's take was shipped to Hon. R. D. Hume, Wedderburn, Oreg., to be hatched and liberated by him in the Rogue River at that point. The balance of the eggs hatched at the station with a loss of 11.10 per cent, and on December 14 the first plant of fry was made. Early in the winter an effort was made to feed a lot of 100,000 in the rearingtanks, but by January 26 the weather became so cold that it was impossible to keep the water running and the fry were liberated. Plants of fry were made from time to time during the winter, though as many as could be accommodated were retained for rearing to the fingerling stage, the last of them being released on May 22. The food given these fish consisted entirely of canned salmon, and they seemed to thrive on it until they were about 2 months old, after which time they began dying in large numbers and were immediately distributed.

The Elk Creek Substation was again operated for the collection of eggs of the steelhead and silver salmon. A dam 125 feet long and 10 to 15 feet wide was constructed in the creek about a mile from the hatchery, the old location 10 miles above the station having been abandoned, as it was found that a large number of the fish spawned before reaching that point. The dam was very solidly built of logs and rocks, with false and solid aprons alternating. The false aprons were filled with rock to give the necessary weight, and around one end of the dam a 4-foot channel was blasted and a trap placed in it. Toward the center of the dam were bowlders, around which the fish jumped, and it was found that by putting a slide upon some of these the fish would fall into it and be carried into the trap on the opposite end of the dam. Only one trap was in operation at the opening of the season, but later the number was increased to three. A series of substantial live-pens was constructed above the dam.

Between the 18th of November and 6th of December 500,000 silver salmon eggs were taken from 268 females. These hatched with a loss of 63,000 eggs, and in April 424,530 fry were deposited in the Rogue River at Trail, Oreg.

The steelhead work opened February 18, but the conditions early in the season were all unfavorable. There was a scarcity of males, and in many instances it was necessary to impregnate the eggs of several females with the milt of a not fully matured male. The weather was also cold and rainy and the water higher than normal. At the close of the season—May 11—the total collections amounted to 617,000. The number of ripe females used was 290. As soon as the eggs had developed sufficiently 481,000 were shipped on assignment, one case of 25,000 being forwarded to an applicant in Germany. The loss on the 126,000 eggs retained for hatching was very heavy, only 20,250 fry resulting from them. These were released in the Rogue River on May 29. The method of taking and fertilizing the eggs was the same as in previous years, and the heavy mortality during incubation is attributed to the unfavorable conditions existing during the collecting season.

LITTLE WHITE SALMON STATION, WASHINGTON.

Although a substation of Clackamas, this station is more important than the head station in all branches of the work. From it are operated the substations on the Big White Salmon River, and also on Eagle and Tanner creeks.

The station was opened July 9, when the usual preparations for active work were commenced. The hatchery and troughs were put in good condition, a combined wood-shed and storeroom was erected, and four skiffs for use at the station and substations were built. All of the buildings were whitewashed and the outside of the window frames given a coat of paint. The dam in the supply creek was partly torn out and widened, with the view to giving an easier outlet during winter freshets. The mess-house, which had been almost against the hatchinghouse, was moved to a distance of 30 yards from the latter to lessen the danger of fire. A new flume was built from the source of the water supply to the filter, and thence to the upper hatching-house; it was then laid along this building to the lower house, and from there to the outside troughs. A scow was made for use in bringing in supplies and for the distribution of fish and eggs.

On August 5 the upper rack was completed, and the work of putting in the other racks was at once pushed to completion. The racks were constructed in the usual temporary manner of tripods with one long and two short legs, weighted, and tied with stringers, upon which the pickets of 2 by 2 material were nailed in a vertical (angular) position.

The fish were captured by means of the regular downstream traps, and after being caught they were held in retention pens until the following day, when they were spawned.

The spawning was done by the use of a spawning-box to hold the fish, which were stunned before being put into the box. The eggs were pressed from the fish by one man into a pan held by another, and the milt was immediately applied. The mixture of milt and eggs was stirred with the fingers, and then the spawn-taker added water until the eggs were barely immersed. After this the pan was set aside for 13 minutes before being taken up and washed. The eggs were then carried to the station in buckets, 15,000 to the bucket, and there they were measured and placed in hatching baskets. After the eggs had been cleaned and picked for a period of 4 or 5 days, they were covered and allowed to remain in perfect quiet until 30 days old, when they were thoroughly washed and picked over. After this picking they were kept perfectly clean until hatched. Feeding was begun before the yolk-sac was absorbed. At first, with the view to accustoming the fry to food, only pure and very finely ground liver was given, but later on, as soon as they began taking food well, they were fed a mixture of liver and mill-feed.

It was necessary to plant many of the fry as soon as they were hatched, on account of lack of water and space, but as many as possible were held and fed until late in the spring, the final distribution taking place during April. The total collections during the season amounted to 14,166,132 eggs, on which there was a loss of 2,537,200.

In addition to the eggs taken at this station, 573,000 were received from the Big White Salmon substation and 598,868 from the Eagle Creek substation, making the total of eggs handled 15,338,000, from which were hatched 12,800,800 fry. The fry loss amounted to 719,995, and the total number available for distribution amounted to 12,080,805, which were scattered along in waters tributary to and in the Columbia River from a point 30 miles up the Des Chutes River to the Sandy River.

BIG WHITE SALMON STATION.

When this station was visited it was found that the White Salmon Boom and Improvement Company had thrown a wing dam across the mouth of the river and had cut a channel across the bar in order to get logs out on a lower stage of water than had been the former practice. This change necessitated new plans for capturing the fish in the river, as it gave the fish a new lead from the Columbia and threw the current from the eastern to the western side of the river.

On September 5 the run of logs was finished and Mr. G. H. Tolbert was placed in charge of the substation with a crew of 2 men. As there are no buildings at this point, the necessary camp equipment was transferred from the Little White Salmon Station, also a complete equipment of tools. Camp was pitched within 300 yards of the mouth of the river, and the fishing-ground was located 500 yards from its mouth. Fishing was conducted by racking the stream and by downstream traps. Old troughs were freighted from the Little White Salmon Station and set up on Olsen Creek, a small stream 1 mile below the mouth of the Big White Salmon River. Here a fine water supply was available, which was not only clear at all times but never varied in temperature.

Later in the season it developed that there was not sufficient room for the fry being collected, and 100 new troughs were made for this station and set up out of doors. They were supplied with water from a 500-foot flume temporarily but substantially built, as it was necessary to carry the flume in one place 20 feet from the ground, exposed to high winds.

The first females were taken September 14, when 29,500 eggs were secured. The fish were captured during the greater part of the season in the downstream trap, but owing to high water it was necessary at times to seine them. The same manner of handling the fish was in vogue as at the Little White Salmon. During the season 872 females were taken, from which were secured 3,415,000 eggs, showing the average production per fish to have been 3,916. From the eggs taken at this station, and from the 741,932 taken at Tanner Creek and shipped to this point, there were hatched 3,075,000 fry, which were distributed with a loss of 330,500. Considering the fact that there were no buildings at the station and that it was but the second year of operation, and also that it was impossible to start the work until late in the season, the results are considered very good.

At Eagle Creek the eggs collected were eyed in troughs set up temporarily and supplied with water by a flume from the creek. Owing to the rough bottom of the creek it was impossible to follow any definite method of fishing, but so far as possible the fish were caught in downstream traps. The traps could hardly deserve the name, being nothing more than slats and slabs placed wherever practicable between the bowlders. Besides these traps, seines and dip nets were used.

The total number of eggs collected amounted to 715,000, which were secured from 146 females, an average of 4,897 per fish. Of these, 90,132 were lost during the period of incubation, 598,868 eyed eggs were shipped to the Little White Salmon Station, and 26,000 eggs were left at the point of collection and planted in Tanner Creek.

The station was cared for throughout the season by two men, and, considering the fact that it was operated for the first time, the work is thought to have been very successful.

At Tanner Creek troughs, lumber, tools, tent, and a complete outfit were set up which had been sent over by boat from the Little White Salmon Station.

The fish were caught by means of racks and downstream traps, and troughs were set up beside the creek in a most temporary manner, with a flume 700 feet in length leading to it from the creek as a water supply.

The first eggs were taken September 12, when 6,000 were obtained from 2 females, and from this date the collecting season continued with an average daily take of 33,516 for twenty-four days. The total take for the season amounted to 804,400, which were secured from 234 females. The loss of eggs during the eying period was 43,468. Of the 786,932 eggs eyed 45,000 hatched before it was possible to get them away from the station, and 741,932 were shipped to Big White Salmon Station to be hatched in the new troughs set up at that place.

The work at this point, as at the Big White Salmon and Eagle Creek, was all done out of doors. The crew of two men lived in a tent, cooked for themselves, and did all the work. The hatching troughs were set up in the open air with no shelter except boards laid across the top of them as covers.

BAKER LAKE STATION, WASHINGTON (H. H. BUCK, SUPERINTENDENT).

The opening of the fiscal year found the racks in place on the river above the lake, as work on them had been diligently prosecuted throughout the preceding month. Seven racks were built, but there were still some sloughs and low places which it was impracticable to

F. C. 1902-6

close entirely at high stages of the water. Notwithstanding the fact that the racks stood and were carefully attended, it was found, as the season advanced, that the fish ascended the river. This makes six years that the problem of blocking the salmon from the upper river has been tried without success. Some other method of capturing the fish must be devised.

During the summer 100 new egg baskets were made of wire with $5\frac{1}{2}$ meshes to the inch, and these proved more satisfactory for hatching blueback-salmon eggs than the former size of 5 meshes to the inch.

The spawning season of the blueback salmon opened September 5 and lasted until October 26. Low water, which had prevailed throughout the summer, continued, and the run of fish in the lake was the smallest that has been noted. In all, 3,694,000 blueback eggs and 50,000 quinnat-salmon eggs were secured, which hatched with a normal loss of 8.7 per cent. These were all planted as fry in the waters of Baker Lake between February 22 and Jure 4.

Silver salmon, as usual, spawned in large numbers in the sloughs at the head of the lake, but no attempt was made to collect eggs from this species because it is not thought best to allow them to dispute the limited area of Baker Lake with the more valuable bluebacks, and there are no facilities for transporting the eggs from the hatchery to other points for distribution.

Early in December the auxiliary station at Birdsview was opened under the direction of Mr. Henry O'Malley, and preparations were made to collect eggs of the steelhead trout from Phinney and Grandy creeks. The heavy winter rains made the maintenance of the racks difficult on Phinney Creek and they were twice washed out. The temporary hatchery erected at this point last year was used as a base of operations, but the greater number of eggs were secured on Grandy Creek, and considerable inconvenience and a heavy loss of eggs resulted in transporting them over the 5 miles of rough country which separates the creeks. It is recommended that the temporary hatchery be removed to Grandy Creek. In all, 408,000 eggs were collected and hatched, with a loss of 18 per cent. Of the resulting fry, 110,000 were planted in the tributaries of the Skagit River during the last days of June and 223,815 were on hand at the close of the year. Details of distribution.

SEA LIONS AT CLIFF HOUSE, SAN FRANCISCO.

PUPS ABOUT FOUR WEEKS OLD.

REPORT ON THE INQUIRY RESPECTING FOOD-FISHES AND THE FISHING-GROUNDS.

By HUGH M. SMITH, Assistant in Charge.

COASTAL AND MARINE INVESTIGATIONS AND EXPERIMENTS. FISHES AND FISHERIES OF HAWAIIAN ISLANDS.

Reference was made in the report for the fiscal year ending June 30, 1901, to the party sent by the Commission to the Hawaiian Islands to make the investigation of the fisheries of those islands called for by the act of Congress of April 30, 1900. The investigations were carried on during the summer of 1901 and completed as far as the circumstances permitted. Most of the islands were visited; the fishery methods, appliances, laws, and customs were studied; a thorough statistical canvass of the commercial fisheries was made, and a very large and valuable collection of fishes was obtained. A preliminary report on the investigations submitted to the President in January, 1902, and by him transmitted to Congress, was printed as a special document (H. R. Doc. No. 249, Fifty-seventh Congress, first session).

It having been determined to continue the investigation of the aquatic resources of the Territory, more especially those in the deeper water, the steamer *Albatross* was detailed for the work, and Dr. D. S. Jordan, of Stanford University, was given general charge. The *Albatross* was fitted out in San Francisco, and sailed for Hawaii on March 11 with a party of naturalists, mostly from Stanford University. The vessel was engaged in this service at the close of the fiscal year.

DESTRUCTIVENESS OF SEA LIONS.

For a number of years the damage supposed to be done to fish and fishing gear by sea lions has been receiving much attention from the fishery interests of the west coast, and the systematic killing of the sea lions has been undertaken in some localities and planned in others, under either State or private auspices.^{*a*}

The following article, from the San Francisco *Bulletin*, is a fairly conservative statement of the fishermen's views:

Fishermen of the North Pacific coast are undertaking a movement for the destruction of the sea lions, the inveterate enemies of salmon and other food-fishes, and which annually make incalculable rayages in the schools of chinooks, steelheads,

^a According to an official communication, dated January 29, 1903, received through the Department of State from Mr. Victor E. Nelson, United States consul at Bergen, Norway, similar charges are made against the Greenland seal (*Phora grentundica*). It is stated that "the cod have been driven entirely away from those parts of the coast (of Norway) where the seals appear in great masses, and the Government has included in the budget the sums of 4,000 kroner (\$1,072) for killing the seals and 15,000 kroner (\$2,000) for other repressive measures.

and other varieties of salmon that hover off the Washington and Oregon coast. The last Oregon legislature passed a bill offering a bounty of \$2.50 for each sea lion killed in the waters of the State or within one marine league of the Oregon shore. Faulty wording of the bill renders the money set aside for the purpose unavailable, and the Fishermen's Protective Union has raised a fund by private subscription to hire men to shoot the lions at their breeding-grounds.

How many salmon each of these monsters kills each day is purely a matter of conjecture, but instances are known where a single sea lion has killed and eaten 18 salmon within a very few minutes, and it is certain that many hundreds of thousands of royal chinook salmon are killed every year by these pests. When fishing, the lions usually travel in groups of from six to eight, and they will follow a school of fish for days. They feast on the fish until they become quite dainty, and will take but one bite from the choicest part of the salmon, leaving the remainder of the fish to float ashore or to be devoured by the scavengers of the seas. The lions vary in size, but when fully grown average about 8 or 10 feet in length, although specimens have been seen fully 18 feet long and which would weigh 4,000 pounds.

It is during the summer months that the lions do the greatest amount of damage. They are numerous at many places along the Pacific coast, but their favorite rendezvous appears to be in the neighborhood of the mouth of the Columbia River. Thousands of them congregate at Seal Rock light-house during the breeding season. These rocks are situated well out from the beach and can be reached only during the extreme low tides of the summer months, thus rendering the retreat of the lions comparatively safe from attack except during isolated periods. After leaving the rocks at the close of the breeding season the lions are even more voracious than usual, and the schools of fish in that region of the ocean have short shrift. Numbers of the lions gather off the mouth of the Columbia River, and the sands of the jetty are black with them during the warm hours of the day. The huge mammals appear to be warned by instinct of the approach of a school of salmon, which is always the signal for a hurried putting to sea, and before the return thousands of the choicest fish in the world have been devoured or so badly mutilated that they will die.

Commercially the sea lions are of little value, and not enough can be realized from their sale to make the killing of them profitable. This, coupled with the extreme difficulty of securing the carcasses of the animals, as the lions take to the water as soon as they are shot, makes the hunting of them a precarious means of livelihood and renders it absolutely necessary that a bounty be paid if the lions are to be exterminated. The hides, which weigh when green about 70 pounds, sell for half a cent a pound. The whiskers of the male sell for from 10 cents to 13 cents for the largest, which are from 10 to 12 inches in length. Those of the female are fewer in number and less valuable, but longer, some reaching 18 inches in length.

A vast amount of valuable fishing gear is destroyed each year by the lions. A big male lion, while in pursuit of a salmon, will become entangled in a gill net or trap, and before it can possibly be released will, by its desperate lashings and biting, tear the web into shreds. The amount of damage done each season would be difficult to estimate, but it is certainly enormous, and their extermination at the least would be of untold benefit to the fishing industry of the coast.

In California the State board of fish commissioners espoused the cause of the fishermen and strongly advocated a reduction of the size of the sea-lion herds on the California coast. As the sea lions can be killed most expeditiously when resorting to rookeries for breeding purposes, and as the rookeries are mostly on islands which are Government reservations under control of the Light-House Board, the California commissioners sought permission for their agents to visit these rookeries and thin out the herds. The granting of this request was opposed

STONES FOUND IN THE STOMACH OF A SEA LION, POINT ARENA, CALIFORNIA.

SPECIMENS OF SALMON FROM GILL NETS, ASTORIA, OREG., SUPPOSED TO HAVE BEEN MUTILATED BY SEA LIONS.

by representatives of the Fish Commission, the Department of Agriculture, and other branches of the Government, on account of lack of evidence showing the destructive habits of the sea lions; and the desired permission was withheld by the Secretary of the Treasury.

Dr. C. Hart Merriam, of the Department of Agriculture, contributed the following article to Science for May 17, 1901, based on the action of the California authorities:

FOOD OF SEA LIONS.

The California State board of fish commissioners during the past two years has taken steps to kill off a very large number of sea lions on the California coast, on the ground that these animals are highly destructive to the salmon fishery. The president of the board, Mr. Alexander T. Vogelsang, claims that it is not the intention of the board to exterminate the sea lions, but merely to kill "10,000 of the 30,000 that now infest our harbor entrance and contiguous territory."* The opinion of observers familiar with the sea-lion rockeries is that the number of animals has been greatly exaggerated, and that long before Mr. Vogelsang has killed the contemplated 10,000 there will not be a living sea lion left on the whole coast. Already many have been killed, and, unless public sentiment is aroused to check the movement, some of the most interesting rookeries of the State are in danger of depletion. The fish commissioners have employed men to shoot the sea lions, and are loud in their lamentations because the Government light-house reservations have not been thrown open to the slaughter.

The local fisherman, the State fish commission, and others assert without qualification that the sea lions feed extensively on salmon, and the inference from their statements is that the animals subsist chiefly, if not entirely, on fish. A few years ago, when similar complaints were made against the fur seals, I took the trouble to examine the stomach contents of a large number of these animals, and found to my surprise that the great bulk of their food consisted of squids, hundreds of whose beaks and pens were found in the stomachs, while in only a few instances were any traces of fish discovered.

In 1899 a well-known naturalist, Prof. L. L. Dyche, of the University of Kansas, spent the months of June, July, August, and September on the California coast, at a time when the sea lions were being slaughtered in the alleged interests of the fishermen. Professor Dyche became interested in the question of their food, and took the trouble to examine the stomachs of twenty-five sea lions, not one of which contained so much as a trace of fish. The region visited extends from Monterey Bay southward along the coast for about 25 miles.

Between June 25 and July 16 there were washed ashore within 3 miles of Point Pinos, at the mouth of Monterey Bay, eight sea lions which had been shot, the fishermen said, because they were feeding on salmon. Professor Dyche examined the stomachs of all of these and has given me a detailed record of the contents of each. It would take too much space to print this in full. Suffice it to state that the remains of squids and cuttlefish (*Octopus*) were found in all, and that several were filled with large pieces of giant squid. Notwithstanding the fact that at the same time and place salmon were being caught by fishermen, not a fish scale or bone was detected in any of the stomachs. Whenever possible Professor Dyche opened the stomachs in the presence of the fishermen, who invariably expressed the greatest surprise at the result.

On July 20 Professor Dyche moved his headquarters southward and established a camp about 12 miles below Monterey Bay, between Point Carmel and the light-house, near which is an extensive rookery of sea lions. Between July 20 and August 16 the stomachs of seventeen additional sea lions were examined. Eight out of the

^{*}In a letter to Hon. Lyman J. Gage, Secretary of the Treasury, dated San Francisco, June 3, 1899. F. C. 1902—-8

seventeen were well filled with the flesh of the giant squid; two were gorged with large octopus, while the remaining seven contained pens and beaks of squids, the quantity varying from half a pint to about a quart.

Professor Dyche was told that there were no fish within 2 or 3 miles of the sea-lion rookeries near his camp, as the sea lions had caught or driven them away. In the face of this statement, he himself caught a dozen rock-cod one morning between shore and the seal rocks, and his boatman, George Carr, an old salmon fisherman, caught plenty of rock-cod weighing from 1 to 8 pounds each within 60 feet of the flat rock where from 1 to 300 sea lions landed each day. The water close to these rocks, where sea lions had lived for ages, proved to be the best fishing-ground in the locality. Professor Dyche states further that he landed a number of times on the rocky islands where in places the excrement from the sea lions formed a layer a foot thick. He hunted through this for fish bones and scales, without being able to discover a single one. On the other hand, the tough pens from the backs of the squids were abundant.

Professor Dyche found the fishermen loud in their denunciation of the sea lions on account of their alleged destruction of salmon, but, although he was on the fishing-grounds continuously for more than three months, the fishermen were unable to show him a single instance in which a sea lion had killed a salmon. He adds: "You can hardly imagine the surprised look on these fishermen's faces when they saw the great masses of squid meat roll out of the sea lions' stomachs when cut open."

The fact that sea lions in captivity will eat fish rather than starve has little bearing on the question, and the additional fact that sulmon in nets are sometimes found bitten off or eaten is by itself no evidence at all, particularly in places where either sharks or otters occur. It is not claimed that sea lions in their native element never eat fish; at the same time the only actual evidence we have on the subject fails utterly to substantiate the allegations of the fishermen. On the contrary, all of the twenty-five stomachs of sea lions examined by Professor Dyche contained remains of squids or cuttle-fishes, and not one contained so much as the scale or bone of a fish. And is it not significant that in former years, when sea lions were much more plentiful than now, salmon also were vastly more abundant? If the fishermen will look into their own habits and customs during the past twenty-five years, it is believed that the cause of decrease of the salmon will not be difficult to find, and this without charging the decrease to the inoffensive sea lions, whose rookeries constitute one of the greatest attractions to the visitor on the California coast.

In 1901 the California board of fish commissioners again brought up the subject and asked that the United States Fish Commission investigate it. The Commissioner accordingly addressed the following letter to the chairman of the Light-House Board, under date of June 6, 1901:

Respectfully adverting to correspondence between the Light-House Board and this Commission regarding the killing of sea lions on Government reservations on the west coast under supervision of the Light-House Board, I have to advise you that this Commission has been asked by the board of fish commissioners of the State of California to make an investigation of the food and feeding habits of the sea lions on the Californian coast, and that the Commission is disposed to accede to the request of the State authorities, in order that the question at issue may be definitely settled by competent official authority.

I have therefore to request that you will cause to be issued the necessary orders to the keepers of light-house reservations, permitting a duly selected scientific assistant of this Commission, with such associates or aids as he may require, to visit the reservations and make the desired investigations, including the killing of a limited number of animals.

I need hardly assure your board that under the desired permission only the minimum number of sea lions required for the settlement of the question will be killed by the Commission's agent.

The Treasury Department made a favorable response to this request, and steps were taken to begin the inquiry at once. Mr. Cloudsley Rutter, scientific assistant of the Commission, was placed in charge of the investigation; and the California board of fish commissioners and the California Academy of Sciences were asked to nominate representatives to cooperate with Mr. Rutter. In accordance with this invitation, Mr. Robert E. Snodgrass was named by the California Fish Commission and Mr. Edwin C. Starks by the California Academy of Sciences. The instructions issued for the conduct of the investigation called for a consideration of the following subjects: The species of sea lions on the California coast, their characteristics, size, distribution, and general habits; the number and location of the rookeries, and the number of sea lions resorting to each rookery; the food and feeding habits of sea lions, in salt and fresh water, at all seasons; the times and places of the appearance of sea lions in fresh water; the damage to fishing apparatus occasioned by sea lions.

The inquiries were begun July 10 in Half-moon Bay, San Mateo County, about 18 miles south of the Golden Gate. Here Pillar Point and vicinity and the Purissima rookery were visited. This is the only rookery where accurate count of the sea lions can be made, and it was kept under observation throughout the year, semimonthly records being made. From the 13th to the 16th of July the rookery at Ano Nuevo (about midway from Half-moon Bay to Monterey Bay) was under observation, and a number of sea lions were here killed. This is the only rookery which can be visited except during the most favorable weather, and is well suited for the study of feeding and breeding habits.

After leaving Ano Nuevo the party divided, Mr. Rutter going north and Messrs. Snodgrass and Starks south. The latter visited Santa Cruz Island, where a number of specimens were obtained, and also other islands of the vicinity, all the rookeries being located with the aid of seal hunters, although most of the rookeries were deserted at that time. Early in August the rookeries near San Pedro were inspected, and later the fishing stations farther south were visited and the fishermen and seal hunters were interviewed. The inquiries were brought to a close by second visits to the Purissima and Ano Nuevo rookeries, August 26 to September 1.

Mr. Rutter spent a week at the Farallone Islands, but was unable to reach the rookeries owing to rough weather, and a later attempt was also unsuccessful. At Point Arena four sea lions were killed and examined. Some time was then spent at the mouth of the Columbia River, where sea lions were under observation from fishing scows and the jetty, and many persons interested in the fishing industry were interviewed. Rough water prevented a visit to the Tillamook rookery. After visiting various points on Puget Sound and Straits of Fuca, Mr. Rutter joined the other members of the party at San Francisco.

Following is the substance of the report submitted by Messrs. Rutter, Snodgrass, and Starks, the description of rookery sites and data on the general habits of the sea lions being omitted. It will be seen that while much has been established regarding the question at issue, further inquiries should be addressed to some aspects of the subject.

REPORT ON THE SEA LION INVESTIGATION, 1901.

The Steller sea lion (*Lemetopias stelleri*) was found at Ano Nuevo Island and northward, and the California sea lion (*Zatophus californianus*) in the Santa Barbara Channel and southward. The Steller sea lion is reported to breed on San Miguel and Santa Rosa islands, but this could not be verified, owing to the rookeries being deserted at the time of visit.

Following is a tabulated statement of the stomach contents of 42 sea lions, 18 of the species *Eumetopias stelleri* and 24 of the species *Zalophus californianus*. An examination of this table shows, among other things, the following points:

1. Of the 26 sea lions whose stomachs contained food, fish remains were found in 18 and squid or octopus in 15.

2. All of the 13 Steller sea lions whose stomachs contained food had eaten fish and 5 had eaten squid or octopus. The number of squid eaten was small, 6 being the maximum number in 1 sea lion, while the quantity of fish was large, at least 35 pounds being taken from 1 stomach.

3. Of 13 California sea lions whose stomachs contained food 5 had eaten fish and 11 had eaten squid. The quantity of fish was inconsiderable, 17 small fishes being the maximum, while the remains of 100 to 300 squid were found in each of 5 stomachs.

This study, as far as it goes, indicates that the Steller sea lion is largely a fish consumer and the California sea lion is chiefly a squid eater. It seems apparent, however, that either species feeds on whatever is most convenient.

Very little positive information was obtained regarding the damage done to the fishing industry at southern points. On one trip made with the fishermen a net was found torn in one place, but there was no proof that the injury was done by sea lions. The testimony of the fishermen was so contradictory that it is of no value. One fisherman claims that in securing \$3 worth of fish his net was damaged \$75, while another claims that there is very little damage done by sea lions. One man holds that the sea lions are becoming more numerous and destructive every year, while another claims that they are rapidly becoming exterminated.

In former years the fishermen in the vicinity of San Francisco complained a great deal about the sea lions, but there was practically no complaint at the time of the investigation. Sea lions were scarcely ever seen in the vicinity of the salmon nets during the year 1901.

At the mouth of the Columbia River, as elsewhere, the direct evidence obtained on this point is meager. Sea lions were seen fishing in considerable numbers about the shoals near the jetty at the mouth of the river, but none was seen to catch a fish of any kind. Gulls were frequently observed hovering about a group of sea lions and acting as if picking up food. One such flock of gulls was seen coming gradually nearer the jetty from a group of sea lions about a mile away; after a time, it was shown that they were following a large piece of salmon flesh which the tide brought within 20 feet of the observer. Salmon were seen and photographed that had been mutilated (presumably by sea lions and seals) after being caught in gill nets. Such mutilated specimens were common. The fishermen stated that the seals simply pull off the gills, but the sea lions always take a bite out of the belly of the netted salmon.

A number of pound nets were visited, but no sea lions were seen in them.

A PART OF THE AÑO NUEVO ROOKERY.

PURISSIMA ROOKERY.

The following is a statement of the number of times sea lions entered various pound nets set in the mouth of the Columbia River, as reported by the owners:

| Owner. | No. of traps. | No. of times entered. | Owner, | No. of traps, | No. of times entered. |
|---|---------------------------------|-----------------------------|--|------------------------|-----------------------------|
| C. Oleson B. Hawkins C. Davidson C. Johnson N. Fodrop F. Gardner | 6 9 1 2 2 2 2 | 4 3 1 4 2 4 | G. Johansen B. Sutherland W. B. Donaldson. Sam Oleson Total. | 2 2 2 2 30 | 1 6 3 3 3 33 |

The fishermen were unanimous in their denunciation of the sea lions. A fishing company at Chinook, Wash., states that it was damaged \$1,500 in 1901 by sea lions letting fish out of the nets, the damage to the nets not being included. The sea lions enter the traps in the same way that fishes do, and, after eating what they wish, break their way out through the side.

Sea lions were not found in Puget Sound in 1901, and no complaint whatever was made concerning them.

It appears from the above that the sea lions are doing very little damage anywhere, excepting at the mouth of the Columbia River. The shallow water and the large number of salmon make that point a favorite feeding ground, and there is no doubt that the sea lions are doing much damage there.

Table of stomach contents of sea lions-Continued.

 \times Indicates that the forms mentioned were present, but their number could not be determined.

a Several "sea pens." b Few. c Unrecognizable material. dShell apparently empty when swallowed.
 e Filled with clear liquid, in which floated a light, yellow, flaky substance.

The following additional information regarding the number of sea lions on the California coast has been submitted by Mr. Rutter:

In 1902 the Ano Nuevo rookery contained 150 pups, which would indicate as many adult females. As there are more males born than females, there is no apparent reason why there should not have been as many adult males, so that the adults of the herd certainly numbered 300, not including the 1 and 2 year old individuals. The number of pups could not be determined at any of the other rookeries, and there is, therefore, no basis of estimating the number of adults at any point except at Purissima, where the adults themselves could be counted. But as Purissima was not a regular breeding rookery in 1901 and 1902, and as it is probable that many of the Ano Nuevo sea lions spent part of the year there, the Purissima counts can not be relied upon for statistical estimates. The most that can be said is that there were several more sea lions at Point Arcua than at Ano Nuevo Island, and that there were several

times as many at the various Farallon rookeries. Probably half the sea lions of California are found at the Farallon Islands, and it seems doubtful whether the total number on the coast amounts to 5,000.

During the breeding season of 1901 there were about 400 adults at Ano Nuevo rookery. The larger males began leaving in July, and were followed by the younger males, and these by the cows and pups. The rookery was entirely deserted by the first of September, and remained so till the middle of the following May, the beginning of the next breeding season. Such was not the case with the Purissima rookery, however. This was not an important breeding place, though a few sea-lion pups were found there in 1901 and also in 1902.

The Purissima rookery is located on a single flat-topped rock lying close to a high bluff, affording an excellent opportunity for observation. Mr. James Mosconi, an employee of the Light-House Service, was engaged to make a count of the sea lions on this rookery at regular intervals, and his figures are as follows:

| Date. | No. | Date. | No. | Date. | No. | Date. | No. |

THE REARING OF LOBSTERS.

Profiting by the experience gained from the previous season's observations and experiments in rearing lobsters, the Commission, during the spring and summer of 1901, made substantial progress in this important work. It having been shown that the station at Wickford, R. I., on Narragansett Bay, afforded better facilities and conditions for lobster rearing than did any of the other stations occupied in 1900, the experiments of 1901 were chiefly conducted at that place, where, as heretofore, the Commission cooperated with the Rhode Island Fish Commission, represented by Dr. A. D. Mead.

The essential factors in lobster rearing are (1) to keep the larval lobsters in motion so they will not settle to the bottom of the retaining vessel and there suffocate or devour each other, and (2) to provide them with suitable food so they will grow and molt quickly and take on the habits of the adults. The vessel in which young lobsters may be best held was devised only after much study and experimentation.

The following report of Dr. H. C. Bumpus, who directed this work, may be advantageously quoted as to methods and results:

Large salt-water ponds, small pools, artificial pools made by the building of dikes, inclosures made of wire screen and floated, and of wire screen and submerged, huge canvas boxes and cars, cars of scrim floated and anchored at the bottom, glass jars of various sizes, running water in vessels of wood, glass, porcelain, and stone, and various rotary devices, all proved efficient agents for the killing rather than for the rearing of lobster fry. After many experiments a relatively simple and inexpensive device was adopted. Several bags of scrim about 3 feet in diameter and 4 feet in

depth were so suspended in the pool of the floating laboratory that the current could not change their general shape or cause them to collapse. In each bag was placed a dasher, the blades of which in rotation would constantly lift the water through the mesh at the bottom of the bag and urge it with obviously less velocity through the pores of the vertical walls. The dashers were kept in motion by means of a small gasoline engine. We found that when the mechanism was in actual operation, the current, in rising through the bottom of the bag, brought with it large numbers of pelagic animals, while the reduced current of the water passing through the greater expanse of the vertical walls was not sufficient to carry this living material out of the bags; thus the apparatus sufficed not only for keeping the fry and artificial food from the bottom, but also provided the fry with living natural food. To Mr. G. H. Sherwood is due the credit of devising and installing this aerating and feed apparatus.

In practice it was found that the eggs stripped from the abdomen of the female would hatch in these scrim inclosures under much more favorable conditions than in the McDonald jars. Indeed, I am inclined to believe that a far higher percentage of cggs would hatch in these bags than in the McDonald jars, and I am sure that the young are in a much more healthy condition than when hatched by the older method. Even a superficial examination of the young that have spent some hours in the trituration of the McDonald jars will show that a large proportion of them have the appendages broken, bent, or indented.

The number of fry that were available for the purpose of experimentation during the first season was considerably less than in 1900, and the period of experimental work was also materially reduced. Nevertheless, Dr. Mead, who had the work immediately in charge, reports that by actual count in no case was the number of lobsters that reached the fourth stage less than 16 per cent of the number of ry originally placed in the inclosure. In a few cases it was above 40 per cent, and in at least one case it was as high as 54 per cent. In previous years no experiments had yielded more than a fraction of 1 per cent. The total number of lobsters raised to the fourth stage during the season of 1901 (in the 12 cylinders) was a little more than 9,000.^a

OYSTER-FATTENING EXPERIMENTS AT LYNNHAVEN.

For several years past the Commission has been conducting experiments in Lynnhaven, Va., under the direction of Messrs. H. F. Moore and W. W. Blackford, for the purpose of developing a method by which oysters may be fattened artificially with the same degree of certainty attained by stock-raisers in fattening cattle.

The practice of allowing oysters to fatten on the beds where they are grown is haphazard in its methods and uncertain in its results, and coves and other places where the natural food supply is sufficiently great at all times and under all conditions are too rare to be available to most oyster-growers. Ordinarily there is no difficulty in raising oysters to a marketable size within a reasonable time, but there is often considerable difficulty in producing them in a marketable condition. Frequently a grower will be unable to ship during a large part of the most profitable season because for some reason, which he can not control, the oysters will not get fat. This difficulty often happens unexpectedly, even within the most favorable localities, and causes the grower to hesitate to enter into contracts which he could profitably

^a The results attending the experiments in lobster culture made by the U. S. Commission of Fish and Fisheries, Science, December 27, 1901.

make had he available some method of fattening his oysters as they were needed. To overcome this difficulty in a measure, it has been customary in some places to resort to "floating" or "drinking," which consists essentially of transferring the oysters to fresh or brackish water. That practice, while giving them an illusive plumpness, injures them in both flavor and nutritive value.

The experiments which have been carried on by this Commission have nothing in common with this method, but are designed actually to fatten and improve the oyster in weight, flavor, and food value. The progress of the work has been briefly noticed from time to time in the annual reports of this Commission. Each year the results have approached more nearly the desired end, and during the season 1901–2 the work has been attended with such success that it is considered desirable to give a more extended account of the plant and its operations than has been before attempted. The work, however, is still in an experimental stage, and the financial results have not yet demonstrated the practicability of the method. During the coming season it is believed that the operations can be so simplified and cheapened and the output so increased as to show pecuniary advantages.

The plant at present consists of a 2-acre pond having an average depth of $2\frac{1}{2}$ feet. Originally it was a cove with a narrow mouth, giving tidal communication with the main body of Lynnhaven Bay. Across the mouth a substantial dam has been constructed of such height as to exclude all save exceptionally high tides. There is some drainage into the pond from the surrounding land, so that after it was dammed it became practically a claire according to the French method.

During the first season of its operation oysters were spread on the bottom of the pond in limited numbers, but there was practically no improvement in their condition during the season, and it was evident that the diatoms, which constitute the principal food of the oyster, would not multiply to a measurable extent under these conditions. In the meantime laboratory experiments carried on in Washington had demonstrated that the growth and multiplication of these microscopic plants, like that of other vegetable organisms, could be stimulated and increased by using certain salts in solution; in other words, by the application of fertilizers to the water in which they were growing. During the following year ordinary commercial fertilizers, such as are commonly used for potatoes and similar crops, were placed in the pond and the number of diatoms increased very considerably, and during that season about 50 or 60 per cent of the oysters in the pond became reasonably fat, some of them excessively so, but the others remained poor and lean. It was evident, as a result of the season's work, that the food supply was ample, but that for some reason it was not equally accessible to all of the oysters, and a comparison of the conditions in the pond with the open waters of the bay indicated that the cause probably lay in the absence of the currents necessary to

transport the diatoms within reach of the sedentary oysters. In the open waters these currents were furnished by the tides, but in the pond there were only feeble currents produced by the winds and local differences in the temperature of the water.

To supply the necessary currents a canal faced with sheet piling was constructed along one side of the pond and communicating with it at both ends. This canal is about 150 feet long and 9 feet wide, and is provided with 16 wooden floats or trays 8 feet 8 inches square and 4 inches deep inside. Each float is capable of holding about three barrels of oysters in a single layer packed nib up, and is hung by ropes attached to small roller windlasses about 6 inches above the bottom. A current through the canal is produced by a propeller at the inlet driven by a gasoline engine connected by rubber belting. During the first year power was supplied by a windmill, but it was found that much power was lost, owing to the frequency of calms and winds too light to carry the load, and the more reliable motor was substituted.

The method of operating the claire is briefly as follows: Before the opening of the oyster season a supply of commercial fertilizer is applied in the shallow water around the edges of the pond, whence it gradually reaches the surrounding water, stimulating a vigorous growth of oyster food. Poor, unsalable oysters are then placed on the floats in the canal and, the propeller being set in motion, a current of about 1 mile per hour is maintained, carrying over the oysters a constant supply of diatoms from the rich store contained in the pond at large. It was found that by this means the oysters in the canal fattened quickly and uniformly, an extremely low proportion of blanks or watery oysters being found.

Owing to the exigencies of experimental work, the utmost capacity of the claire in fattening oysters has not yet been determined, but the fact that one lot was raised from a very poor to first-class condition in eight days indicates that it will be considerable when the proper arrangement is discovered. With the present canal capacity, which could probably be considerably increased to advantage, a maintenance of this rate would give a capacity of about 175 barrels per month, or 1,400 barrels during the season of eight months, from a 2-acre farm. During the past season two difficulties which militated against a true test of the capacities of the ponds were encountered: Occasionally a very slight marshy taste would be noticeable in the oysters, and at such times no shipments were made, for fear of injuring the demand. It has been learned that this can be overcome by the application of lime to the water at the end of the canal. The other difficulty is that in wet seasons with few high tides the water in the pond becomes too fresh and the oysters rather too insipid to bring the highest price in the market. A plan is now under consideration and will be put into operation during the ensuing season which it is thought will obviate this. Under the best conditions, ovsters placed in the pond in an

unmerchantable condition sold after fattening for \$6 per barrel in Philadelphia. It is believed that at the close of the next oyster season definite plans of a plant and a method of operating it can be placed before the oyster-planters of the country. At present the Commission does not feel prepared definitely to recommend the method.

INQUIRY REGARDING DESTRUCTION OF OYSTERS BY DRUM-FISH.

In the latter part of June, 1902, the attention of the Commission was called to the destruction wrought by the drum-fish (Pogonias cromis) in the vicinity of Tuckerton, New Jersey, and Dr. H. F. Moore was at once sent to that place to make an investigation and if possible determine what measures should be taken to mitigate the losses. Ovstergrowing is the main industry of Tuckerton, and most of the available oyster bottoms of Little Egg Harbor and Great Bay are taken up by persons living in that town and its vicinity. Although there is some good spawning-ground in these waters, the industry is mainly dependent on seed brought from other localities. Until within a few years, most of it was brought from Chesapeake Bay and other parts of Virginia, but recently it was discovered that seed from Long Island and Connecticut grew with remarkable rapidity when laid down in that vicinity, and it has since been heavily purchased, almost to the exclusion of other seed. It is stated that in some instances seed ovsters from Great South Bay, Long Island, have incréased 400 per cent in bulk within a period of six months, and to a somewhat greater extent in value.

For several years past the oystermen have sustained losses for which they could account only by attributing them to theft, but in the spring of 1901 it was discovered that the drum-fish was eating the young ovsters in considerable quantities, and during the spring of 1902 the destruction became so great as to demand concerted action upon the part of the oystermen. A meeting was held at Tuckerton, at which most of the principal planters were present, and a fund was created to defray the expenses of fighting the common enemy. Special permission having been obtained from the State authorities, an attempt was made to kill the fish and drive them away by dynamite and nets. The nets used were some that had been discarded by sturgeon fishermen, and had a mesh of about 14 inches extension measure, rather too large for the drum-fish. They were set at random over the oyster beds and at first made fair catches, but their efficiency gradually decreased, owing, the ovstermen supposed, to the fish being frightened away, though it seems very probable that the fish deserted the beds owing to their practical depletion and to their consequent loss of attraction to the fish which came upon them in search of food.

At the time of the visit of Dr. Moore about 100 pounds of dynamite had been exploded during four days' work, and about 1,000 fish of large size had been killed. The dynamite is not used on the oyster beds for fear of killing the oysters as well as the fish, but near the inlet, where the fish school at ebb tide. Two charges of 3 pounds each are attached, 50 feet apart, to a conductor, towed over the schools of fish, and exploded about 4 feet below the surface. On several occasions from 100 to 200 fish have been destroyed at a single explosion, and the survivors within a considerable radius of the disturbance are apparently badly frightened. As the dynamiting takes place at a considerable distance from the oyster beds and in the daytime, however, while the fish appear to feed on the beds principally at night, it is by no means certain that the effects will be very manifest in preventing the destructive inroads. The most efficient way of protecting the beds would, of course, be to inclose them completely with nets or stockades, but, owing to the large extent of the beds, to the navigable character of the water, and to the amount of material which drifts with the tide, this plan is not feasible at Tuckerton.

Some very extensive beds examined by Dr. Moore were found to be practically depleted of oysters. In one case where 15,000 or 20,000 bushels had been planted, and the owner estimated the loss at 50 per cent, an examination of areas selected at random indicated that upwards of 80 per cent of oysters had been eaten by the drum-fish, and nothing remained of them but a few ground-up fragments of shells. On these same beds native seed, owing, doubtless, to its much heavier shell, had not been destroyed. Should the present efforts of the oystermen to protect their beds prove unavailing, it seems probable that the only recourse is to abandon the use of the thin-shelled eastern seed and restrict planting to heavy-shelled varieties. If the beds can be efficiently protected each year for a period of two or three months after they are planted, it is probable that no further trouble will occur, as by that time the seed oysters will be large enough to resist the attacks of drum-fish.

TRIP TO THE TILE-FISH GROUNDS.

On July 28 the schooner *Grampus*, with a small party from the Woods Hole Station, made a short trip to the tile-fish grounds lying off No Man's Land. The grounds were reached during the night of July 28–29, and on the morning of the 29th four tubs of trawls, baited with squid, were set in water 65 to 70 fathoms deep, in latitude 40° 6' north, longitude 70° 24' west, $70\frac{1}{2}$ miles south and one-half mile east from No Man's Land. One part of the trawl, owing to fouling, caught no fish; the other, after being on the bottom for about two hours, was hauled and found to have 62 fine fish, with an aggregate weight of about 700 pounds. The *Grampus* returned to Woods Hole on July 30, and the fish were shipped to dealers in New York, Boston, and Gloucester, who had expressed a willingness to handle them and endeavor to create a demand which would lead to the establishment of a regular fishery.

The reports as to the food value of these fish coincide with those

received in previous years in being unqualifiedly favorable. The following, from Mr. William H. Jordan, collector of customs at Gloucester and one of the leading vessel-owners and fish-dealers, shows the way in which the tile-fish is regarded in the leading fishing port of the country:

The tile-fish arrived in the best of order, having been very carefully prepared, and I distributed them among fourteen of my acquaintances. I have heard from nearly all of them, and they have expressed themselves as highly pleased with the quality of the fish, considering them delicate and of high flavor. I, myself, found the fish exceptionally good, and enjoyed my dinner from it. Certainly it would seem to me that if the people could become familiar with the tile-fish in some such manner of distribution as you have made through me, it would open up a demand for a large quantity of the fish, should they be caught.

The prospects for the inauguration of a special tile-fish fishery from Gloucester, Boston, New York, and several other ports now seems much more promising than at any previous time. The investigations of the Commission have shown a great abundance of tile-fish over a wide area adjacent to our shores and clearly indicate that a profitable industry may be developed.

THE GROWING OF SPONGES FROM CUTTINGS.

The experiments in sponge-culture begun in Florida under the direction of Dr. H. F. Moore during the preceding fiscal year have been continued during the present year, and it is believed that considerable progress has been made toward the development of a practical commercial system of sponge-culture. The constant aim has been to reduce as far as possible the niceties of experimental work to a basis adapted to the requirements of the practical sponger.

As stated in a previous report, several thousand sponges were planted in January and February, 1901, and at the end of six weeks these were found to be growing well. Examination in November, 1901, however, showed that most of the cuttings had died and that some of them had been stolen for the value of the wire to which they were attached. Most of these plants were made upon copper wire, which, while it has the power of resisting to some extent the action of salt water, is in some localities more or less subject to corrosion, and the salts produced are inimical to the sponge, causing it to die near the point of attachment and fall from its support. During the present year it has been sought to overcome this difficulty by using insulated copper wires, so that the cuttings would not be brought into contact with the bare metal. Further improvement was made in slitting the sponge cuttings and placing them astride the wire or other support to which they were attached, and then binding the surfaces of the flap in close apposition by means of a wire. In the course of a few days the two flaps grew together and the cutting became permanently attached, independently of any artificial binding. Temporary tie wires of aluminum wire were

used, which, while slowly acted upon by salt water, lasted a sufficient length of time to permit the sponge to permanently heal.

During the winter months the growth of the cuttings was rather slow, so far as increase in bulk was concerned, although eyes, or oscula, were promptly put out and the circulatory system quickly reorganized and completed. During the spring when the water, especially in the more southern part of the State, was becoming warmer, there were indications of more rapid growth. About six thousand cuttings were planted in Biscayne Bay, Sugar Loaf Key, and in the vicinity of Anclote Keys, and in the latter part of April, after they had been planted for periods varying from two to five months, most of them were growing and in an apparently healthy condition.

Between the lower end of Biscuyne Bay and Matecumbe Key there is a long stretch of water where sponges do not grow naturally. An investigation of this region was made to determine the reason for their absence, and an experimental plant of about a thousand cuttings was made in a small sound back of Key Largo, with a view to determining whether they could be artificially introduced there. At the end of six weeks practically all of these cuttings were dead, although others planted at about the same time in more favorable localities were alive and growing. A series of observations developed the fact that the water in this region is of a much lower salinity than in places where the sponge grows naturally, and it is probable that this is the cause of their absence naturally and of the mortality of the cuttings.

Practically nothing is known of the rate of growth of sponges under natural conditions, or of the rapidity with which they will develop from fragments and cuttings, and it will probably require several years' investigation to determine these points and to develop, if it can be developed, a system of sponge-culture which will be of value to the State of Florida. At the present time the production of sponges in this State, which is the only one in the country producing them, is about \$500,000 per annum. An equal or perhaps greater value of sponges is imported from abroad, and it is hoped eventually to supply this excess of demand over production by sponges raised artificially. Many of the sponge-dealers are showing considerable interest in the experiments, and it is believed that they will promptly undertake sponge-culture if a reasonably practical method can be developed.

SURVEY OF THE FLORIDA SPONGE-GROUNDS.

The steamer *Fish Hawk*, working under the direction of this division, in October, 1901, resumed the survey of the sponge-grounds of the western coast of Florida, and in March, 1902, completed the examination of the waters lying north of Tampa Bay, comprising all those grounds designated under the names "Gulf," "Bay," "Rock Island," and "Anclote." The location of the sponge-grounds has been plotted on charts, and, for the first time, the extent, position, and relations of the grounds have been determined.

The sponge-bearing bottom stretches in a continuous but irregular band or zone, 5 to 35 miles wide, from Apalachee Bay nearly to Tampa Bay, the length, following the curvature of the coast, being about 175 miles. The grounds are widest off Withlacoochee Bay, Deadmans Bay, and Rock Island, and narrowest off Cedar Keys. Three large disconnected areas, between the shore and the sheepswool grounds, on which grass sponges grow rankly to the exclusion of most other kinds, are in or near St. Martins Bay, Deadmans Bay, and Apalachee Bay. It is intended to continue this work by detailing the *Fish Hawk* to

It is intended to continue this work by detailing the *Fish Hawk* to survey and plot the remaining sponge-grounds, of which those about the Florida keys are the most important.

RIVER AND LAKE INVESTIGATIONS.

GREAT LAKES BIOLOGICAL SURVEY.

Prof. H. S. Jennings, of the University of Michigan, directed inquiries addressed to various subjects connected with the animal and plant life of the Great Lakes, in continuation of the work begun a number of years ago. As in previous seasons, Lake Eric was the field of investigation, and the Fish Commission station at Put-in Bay was the headquarters of a party of specialists employed throughout the summer.

Among the fishes specially considered were the white-fish and walleyed pike, by Dr. Raymond Pearl, of the University of Michigan, the carp, by Mr. Leon J. Cole, of the same institution; and the sturgeon, by Prof. S. O. Mast, of Hope College. Mr. Pearl's inquiries had for their object (1) the determination by detailed statistical methods of the existence or nonexistence of different races of white-fish (Coregonus clupeiformis) in the different lakes, and (2) the demonstration by the same methods of the relation of the blue pike to the yellow pike (Stizostedion vitreum) of the Great Lakes. The study of the variations of the white-fish will not be completed for several seasons, owing to the wide field to be covered and the extensive series of measurements of individual specimens necessary for the purpose in view. The work on Stizostedion need not be resumed, as enough has been learned to show that the wall-eyed pike is a species of remarkably low variability and that there are no structural differences between the blue and the yellow varieties, this being in accord with other observations. The continuation of Mr. Mast's examination of the lake sturgeon at the spawning season resulted in the collection of additional information as to the past and present abundance of the fish in the rivers of Michigan, and furnished data of importance in the event of the Commission taking up the artificial propagation of this species in the Great Lakes.

Prof. H. B. Ward, of the University of Nebraska, was in charge of the plankton work. He completed the field tests of the efficiency of the large plankton nets. Further work with these nets should be specially directed to the comparative abundance and food relations of plankton organisms. The small minnows which abound in the plankton region and form a link between the plankton and some of the larger fishes should receive attention at the same time. Prof. Ward also continued his study of the vermine parasites of fishes, assisted by Mr. H. W. Graybill.

Dr. Charles Fordyce, of Nebraska Wesleyan University, was engaged in a study of the small crustaceans of the order Cladocera, which are an important element of the fish food of the lakes.

Prof. F. C. Newcombe, of the University of Michigan, was in general charge of the investigations of aquatic flora. Dr. Julia W. Snow, of Rockford College, continued her work on algae. Prof. R. H. Pond, of the Maryland Agricultural College, completed during the fiscal year his study of the nutrition of the larger aquatic plants. During the summer he assisted Prof. Newcombe in his study of the distribution of water plants in relation to soils in Lake Erie.

For several weeks in April and May Prof. Jacob Reighard, of the University of Michigan, was engaged in studying the breeding habits of fresh-water fishes. The forms chiefly studied were the black bass, the brook lamprey, the stone roller, and the horn dace.

During the year Prof. Reighard and Prof. Ward were engaged in discussing and preparing for publication the results of their work in determining the efficiency of plankton nets. At the same time Professor Jennings studied one of the families of rotifers (the *Rattulidæ*), and prepared a monograph of the family.

A bill "to authorize the establishment of a biological station on the Great Lakes under the control of the United States Commission of Fish and Fisheries" was introduced in the Senate on December 17, 1901, and favorably reported back by the committee on fisheries on April 1, 1902. The report of the committee embodied a communication from the Commissioner advocating the passage of the bill. The bill passed the Senate on May 16, but was not acted on by the House.

THE STATUS OF THE CARP IN THE GREAT LAKES.

With the probable exception of the Illinois River, no body of water in the United States appears to be so well-stocked with carp as Lake Erie. There is also an abundance of carp in Lake Huron, Lake St. Clair, and other Great Lakes. In view of the continued disfavor with which this fish is regarded in some quarters on account of its supposed objectionable qualities, the Commission decided to institute a systematic investigation of the species in the Great Lakes, and assigned to the work Mr. Leon J. Cole, of the University of Michigan, who began his inquiries in the latter part of June, 1901, and continued until the last of November. The points to which special attention was given were the food and feeding of the carp, the relation of the carp to other fishes, the relation of the carp to wild fowl, and the food and market value of the carp. Much information of interest and importance was obtained, but it will require another full season's inquiries in order to render the investigation approximately complete.

The carp investigation was begun in Lake St. Clair, where Mr. Cole went to investigate some statements of a fisherman which were published in the Port Huron (Mich.) *Times* of April 16, 1901. These assertions were to the effect that "the carp eats the spawn and destroys the perch, bass, and other good fish of these waters"; that "the supply (of these fish) is already much reduced," and that "in three years more there will be no fish except carp left in the lake." At New Baltimore and other places on the lake Mr. Cole found the same sentiments prevailing in regard to the carp as those expressed in the newspaper article referred to. Inquiry among the fishermen, mostly eity sportsmen, showed that certain stock charges were made against the carp, and it was not usually claimed that these charges were based on direct knowledge or observation.

The sentiment against this fish in this region was due largely to a belief (1) that the carp thrashes about and stirs up the mud, so that the breeding-grounds of other fish are spoiled; (2) that the carp roots up the vegetation, destroying the wild rice, etc., and thus ruining good duck-shooting grounds; (3) that the carp eats the spawn of other fish; (4) that the carp eats the young of other fish; (5) that the carp is of no value as a food-fish; (6) that the carp is of no value as a game fish.

The fact that black bass and other fish were nesting at this time afforded opportunity to make observations on several of these points. In a small bay where carp were commonly found in the shallow water among the weeds and grasses, there were a number of bass nests. At no time was a carp seen among the bass nests, which were some distance apart and hence covered a considerable area. A fyke net was set with a view to intercept any carp that might cross the tract covered by the bass nests, but with negative results. On several nests young bass were later noticed, and Mr. Cole thinks it probable that more would have hatched if the parent fish had not been speared (in violation of law) or caught with hook and line (in conformity with law), thus leaving the eggs exposed to any fish that might come along. Nests of some of the sun-fishes were found close inshore where carp were common, and these nests contained eggs; when the parent fish were frightened way, it was noticed that swarms of minnows, which seemed to be waiting this opportunity, rushed in and began to devour the eggs.

The observations showed that the carp makes the water very rolly where it splashes about and evidently tears up more or less vegetation, but there was no evidence that the flags often found floating were not torn loose by muskrats or other animals.

F. C. 1902-9

Considerable time was spent at Port Clinton, Ohio, as this is the principal market for carp on the lakes. The wholesale dealers here rendered every possible assistance to Mr. Cole, including all the carp needed for examination and a room in which to work. Many carp were here examined with reference to their food, and the study of various related subjects was made possible by the abundance of material. During the course of the season all important points between Buffalo and Detroit were visited, and the fishermen and dealers in each place were interviewed. Among the data thus obtained was a statement from each wholesale dealer of the quantity of carp received from Lake Erie fishermen in 1900, this representing the approximate catch of carp in the lake. The figures as tabulated give 4,595,000 pounds as the carp product in 1900, an increase of 964,000 pounds over the previous year; of this quantity about 4,069,000 pounds were landed at Monroe, Toledo, Port Clinton, and Sandusky.

Carp ponds at Monroe, near Sandusky, at Port Clinton, and on Catawba Island were visited and information regarding the feeding, etc., of carp was obtained.

In the fall of 1901 the inquiries were addressed particularly to the relation of the earp to the white-fish during the spawning season of the latter, and were conducted at the Bass Islands and Port Clinton. As a basis for the investigation, the following assertions of the fishermen of North Bass Island were taken: Carp are abundant about the Bass Islands when the white-fish are spawning; carp eat the spawn of other fish, especially white-fish; white-fish spawn has been taken from a carp's stomach; when carp are numerous on a reef, the white-fish are not there, being driven away by the carp.

At Port Clinton Mr. Cole made trips to the fishing-grounds with the fishermen and also examined the carp landed by the fishermen; and at North Bass Island examined carp brought in by fishermen using whitefish gill nets on the reefs. He reports that very few carp were caught on the white-fish grounds, and that the result of their examination was entirely negative as to any damage done by carp to white-fish. The evidence indicates that the number of carp on the white-fish spawninggrounds in fall is very small, and the carp which are there have not been found to contain white-fish spawn. The eggs of the white-fish, not being adhesive to any great degree, probably become widely scattered over the rocky reefs; and unless the carp were present in large numbers, the relative number of eggs destroyed would be small. There is no direct evidence as to the destruction of white-fish fry by carp, except that during the entire course of this investigation no young white-fish or any other kind of fish were found in carps' stomachs. Considering the shape of the carp's mouth, the lack of teeth, and other anatomical peculiarities, it seems very doubtful that the fish-eating charge against the carp could be very serious.

FISHES OF CHAUTAUQUA LAKE, NEW YORK.

In September, 1901, this lake was visited by Prof. B. W. Evermann for the purpose of determining its general biological features and the variety and abundance of its fish fauna. A report" on this inquiry gives an annotated list of 31 species of fishes known from the lake. Although this lake is only 8 miles from Lake Erie, it is in the Ohio River drainage basin, and its fish life partakes of the character of the latter. Among the important species are bullhead (Ameiurus nebulosus), rock bass, blue sun-fish, large and small mouthed black bass, and muskallunge. The last named is the leading fish, from the standpoint of both angler and commercial fishermen. Although extensively caught, its abundance appears to be maintained from year to year as a result of limited protection and artificial propagation by the State authorities. It appears from this investigation that the Chautauqua Lake muskallunge is not identical with the muskallunge of the Great Lakes (Esox nobilior), as has generally been held, but is a distinct species (Esox ohiensis) peculiar to the Ohio basin. The two gars or bill-fish (Lepisosteus osseus and L. platostomus), worthless as food and very destructive to other fish, were systematically destroyed by the State Fish Commission for several years and their numbers much reduced.

FRESH-WATER FISHES OF LONG ISLAND, NEW YORK.

During September and October, 1901, Dr. Tarleton H. Bean collected and studied the fishes of Long Island, New York, in the interests of the Commission, with headquarters on Great South Bay. Particular attention was given to the fresh-water species, which, while few in number, are of considerable interest.

The peculiar topographical features of Long Island are responsible for the scarcity of fresh-water fishes. The total number of such fishes known to occur in the streams and lakes is 27. One of these—a hybrid trout—has been artificially produced; another, the black-nosed dace, is of doubtful occurrence, and 13 others have recently been introduced. The permanent residents in fresh water, as determined by Dr. Bean, are horned pout, chub sucker, chain pickerel, killifish, pirate perch, silverside, sun-fish, yellow perch, and darter, all of which could easily have been introduced by man within the last century or two.

Mitchill, in his Report on the Fishes of New York (1814), mentions only the yellow perch, brook trout, and pickerel as occurring on Long Island. Mitchill, in 1790, transplanted yellow perch from Ronkonkoma Pond to Success Pond, Queens County, a distance of 40 miles.

FISHES OF LAKE MASHIPACONG, NEW JERSEY.

Lake Mashipacong lies in the New Jersey mountains about 10 miles south of Port Jervis, N. Y., and covers approximately 100 acres. In

a Notes on the Fishes and Mollusks of Lake Chautauqua, New York. Report U.S. Fish Commission for 1901. October, 1901, Prof. B. W. Evermann made an examination of the lake with reference to its fish fauna. The maximum depth, as determined by numerous soundings, was 14.5 feet. Although fish food is abundant, the larger fishes are limited in both species and individuals.

The following fishes were found to inhabit the lake: Common bullhead (Ameiurus nebulosus), white sucker (Catostomus commersonii), chub sucker (Erimyzon sucetta), roach (Abramis crysoleucas), eel (Anguilla chrysypa), banded pickerel (Esox americanus), common eastern pickerel (Esox reticulatus), and blue-gill sun-fish (Lepomis pallidus). A few large-mouthed black bass were recently planted in the lake, and the conditions seem favorable for their rapid increase.

FRESH-WATER FISHES OF MAINE.

In accordance with a request from the Debsconeag Fish and Game Club that the waters composing the fishing privilege of the club be examined to ascertain why trout attain only a small size and if the lakes were suitable for the introduction of trout and landlocked salmon, Dr. W. C. Kendall devoted the month of August to the study of these waters.

Debsconeag lakes are a chain of five or six small lakes, which from the westward debouch into the West Branch of the Penobscot not far from Debsconeag Falls and about 20 miles from Norcross. Other waters not connected with this chain of lakes, but comprised within the Debsconeag privilege, are Hurd Pond and tributaries and Rainbow Lake, besides a number of smaller ponds and streams. These waters are not exclusively controlled by the club, being public waters, but the club has camp privileges on all of them within certain townships. The water area was found to be so extensive that only superficial examination of all of them could be made, so most of the time was devoted to First Debsconeag Lake and Hurd Pond.

Brook trout are apparently uncommon in Debsconeag lakes and Hurd Pond, but very abundant, though of small size, in Rainbow Lake; in some of the small ponds they occur in fair numbers. Togue (*Cristivomer namaycush*) are doubtless common; some of large size have been caught, but only small ones of 2 or 3 pounds were obtained during the month of August, and these only in Hurd Pond. There seems to be a scarcity of species of the minnow tribe in some of these lakes, and the fish faunas of the several bodies of water seem to differ somewhat in character; for instance, the chub (*Semotilus corporalis*), common in the Debsconeag lakes, was not found in Hurd Pond, but there its place is taken by the brook chub (*Semotilus atromaculatus*), which, so far as ascertained, did not occur in the Debsconeag waters. If the conditions prevailing in August obtain throughout the year, the scarcity and smallness of trout is probably due to paucity of food.

In order to obtain important information regarding small salmon occurring in the East Branch of the Penobscot, mention of which was made in last year's report, Dr. Kendall visited Matagamon Lake, and the East Branch was examined from the dam at the foot of the lake to Stair Falls. The small salmon were found common in the pool below the dam and at Stair Falls. Specimens were obtained by fishing with very small artificial flies, but none over 9 inches long was found. All but one of these fish were males in well-advanced breeding condition, the exception being a female with distinct eggs, but which would not have matured before another fall.

From here opportunity was taken to visit more northern Maine waters to obtain much-needed information regarding the character and distribution of the fish life of this region. Accordingly, a canoe voyage was made from Matagamon via Matagamonsis, Webster, Telos, and Chamberlain lakes to the Allagash River, thence down the stream through numerous lakes to the St. John, and from the St. John a trip was made up the St. Francis to a few miles above Beau Lake and return, thence down the St. John to Fort Kent. It was the intention to haul from here to Cross Lake, thence proceed by canoe down the Eagle lakes or east branch waters of Fish River, up Fish River to Portage Lake, and thence haul to Ashland; but owing to the uncertainty of getting through the proposed route on time, it was decided to bring the explorations to a close after making some collections in Cross Lake. Very interesting collections were made in all the lakes en route, as well as in some tributary waters, and much valuable knowledge was gained.

Some interesting facts regarding the geographical distribution of the Maine fishes were developed. The recorded range of some species was extended into the State, and others already recorded from Maine waters were found in new localities.

At least four species of fishes apparently new to science were obtained, the most interesting and important being a white-fish (*Coregonus*). Two species of white-fish were already known to occur in the State, the round white-fish (*Coregonus quadrilateralis*) and the "attahawmeg" (*C. labradoricus*). The latter is the best known and reaches the largest size. The only locality in Maine from which the round white-fish has hitherto been recorded is Clearwater Pond, at Industry. It was ascertained to be very common in northern Maine.

The little stickleback (*Gasterosteus atkinsii*), for many years known only from a few specimens from Grand Lake Stream, was found to be widely distributed over northern Maine and is not so insignificant as from its size it at first might appear. In the fall it was found to constitute the principal food of the lake trout, or "togue," sometimes to the exclusion of everything else. Many togue were caught gorged with these little fish. *Coursius plumbeus*, until recently not known from Maine waters, was found to be one of the commonest minnows. In the lakes it seems to be a deep-water form, seldom approaching the shore except at night and in breeding season, when it enters streams and shallow water to spawn. This habit and the abundance of the fish would indicate that it must be an important food for larger fishes.

Coherent reports and descriptions of a red forked-tailed trout in some of the waters of St. Francis River suggests the possibility of another char occurring in these waters.

BIOLOGY OF THE SACRAMENTO SALMON.

On the conclusion of the sea-lion investigation elsewhere alluded to, Mr. Cloudsley Rutter resumed the study of the quinnat salmon in the Sacramento basin, on which he had been engaged for a number of years.

The work began September 1 at Black Diamond, California, where by weighing and measuring many specimens of salmon recently from the sea a standard weight was established for fishes at the mouth of the river. Then 150 specimens were weighed, branded with serial numbers, and released, in the expectation that some of them would be taken again at the hatcheries and light thus be thrown on their rate of travel upstream and their loss of weight during migration. Three of the marked fish were subsequently recaptured.

During October two trips were made down the Sacramento River in a skiff for the purpose of charting the spawning-beds and noting the dates at which the beds were successively occupied. November was spent at the Mill Creek hatchery near Tehama, the principal work being the weighing and measuring of salmon in various conditions for comparison with those examined at the mouth of the river.

The run of quinnat salmon in Papermill Creek, Marin County, was investigated, as the species had never been known in that stream prior to the planting of fry there in 1897 and 1898.

The preparation of a general report on the salmon investigations and the study of material with a view to a report on the embryology of the quinnat occupied Mr. Rutter's time during the remainder of the year.

The habits of the Pacific salmons are vitally different from those of the Atlantic species, and as these have an important relation to natural reproduction, artificial propagation, and commercial fishing, the Commission deemed it desirable that the species be subjected to a careful physiological investigation. While the Atlantic salmon, *Salmo salar*, has been studied from the standpoint of physiology,* the Pacific salmons have up to this time been neglected in this respect. The Commission therefore engaged the services of Prof. Charles W. Greene, of the University of Missouri, who has devoted much attention to comparative physiology. Professor Greene began his field work early in July and continued until September, examining the salmon before they entered the rivers and after they reached their spawning-grounds,

^{*}See Investigations on the Life History of the Salmon in Fresh Water, by D. Noel Paton, M. D. Special Report of 1898, Fishery Board for Sectland.

and at intermediate points in the Sacramento basin. Most of the time was spent at Baird hatchery, where there was an abundance of material and where the superintendent, Mr. Lambson, and the foreman, Mr. Wallich, rendered valuable assistance.

INTRODUCED FISHES IN UTAH AND IDAHO LAKES.

Continued public interest in the planting of the Great Lakes whitefish (Coregonus clupeiformis) in Bear Lake (Idaho and Utah), Coeur d'Alene Lake (Idaho), and Pend d'Oreille Lake (Idaho), induced the Commission to make another effort to determine the results of the plants of fry in these waters a number of years ago. Accordingly, in July, 1901, a party, consisting of Mr. S. P. Wires, superintendent of the Duluth (Minnesota) hatchery; Mr. S. L. Pritchard, of the Washington office, and Mr. Dwight E. Miller, was dispatched to these lakes with an equipment of gill nets of various sizes, seines, and other appliances. Fishing was carried on in Bear Lake (and Mud Lake connected therewith) at ten different points and during six days; in Lake Coeur d'Alene at thirteen different points and during eight days; in Pend d'Oreille Lake at nine different localities and during six days. No introduced white-fish were discovered, and no evidence of the existence of this species in any of the lakes was obtained, although three other species of introduced fishes were found.

The water of Bear Lake is reported to be very hard, unfit for domestic use, and possibly unsuited to the white-fish of the Great Lakes, although Williamson's white-fish (*Coregonus williamsoni*) is found in it. During the first week in August the surface temperature of the water in the vicinity of Fish Haven was found to be from 69° to 71° . The minimum bottom temperature determined was 50° , at a depth of 105 feet; fishing, however, was carried on in water 175 feet deep, but no temperature data were obtained therefor. Suckers (*Catostomus macrocheilus*) and chubs (*Leuciscus lineatus*) abound and are the characteristic fishes of the lake; black-spotted trout (*Salmo clarkii*) also occur. Mud Lake is reported to be little more than a marsh during July and August, although it contains some black bass, carp, and a few black-spotted trout.

The water of lakes Coeur d'Alene and Pend d'Oreille is deep and cold, resembling in every respect that of the Great Lakes; and it would seem that the white-fish whose introduction has been attempted should do well in both of them. Besides Williamson's white-fish, many fine specimens of bull trout (*Salvelinus parkei*) 11 to 12 inches long and of the black-spotted trout were found in both these lakes, and suckers (*Catostomus macrocheilus* and *C. catostomus*) are abundant. The introduced species, large-mouth black bass and yellow perch, seem to have become well established in Lake Coeur d'Alene; examples of the latter $10\frac{1}{2}$ inches long were obtained.

MARINE BIOLOGICAL LABORATORIES.

Woods Hole, Massachusetts (Hugh M. Smith, Director).

During the season of 1901–2 the work at the Woods Hole laboratory was under the direction of Dr. Hugh M. Smith, assistant in charge of division. Dr. H. C. Bumpus, who had been in charge of the laboratory for a number of years, was unable to continue his relations with the Commission owing to other duties.

The usual facilities for research and collecting existed, and the rare opportunity for marine biological work here afforded was appreciated by the representatives of many institutions of learning. Two large fish-traps operated for the laboratory in Vineyard Sound and Buzzards Bay furnished much useful material. The steamer *Fish Hawk* and the schooner *Grampus* were temporarily attached to the station during the entire summer, and the steam yacht *Phalarope* and the steam launches *Blue Wing*, *Cygnet*, and *Merganser* were in constant service. The director had the efficient assistance of Prof. R. W. Tower, Mr. George H. Sherwood, and Mr. Vinal N. Edwards.

Among the biologists who occupied tables, the following carried on special investigations in behalf of the Commission:

Dr. Gary N. Calkins, of Columbia University, studied the marine protozoa found in the vicinity of the station. This group of animals has been neglected by systematists in the United States. The protozoa are numerous, and are important as being the ultimate animals on which the higher animals are dependent for food. Dr. Calkins found the water in the immediate vicinity of the station to contain many species and individuals, including a number of species not previously described. His report, published in the Fish Commission Bulletin for 1901, is an important contribution from one who is a leading authority on the subject.

Dr. George II. Parker, of Harvard University, studied and reported on the effects of light, temperature, gravity, currents, and other natural agencies on the movements of copepods. These minute crustaceans are found throughout the year in varying abundance, and constitute one of the most important foods of young and small fishes, young lobsters, and other animals. Dr. Parker's observations and experiments were directed to the determination of the physical factors controlling the appearance and disappearance of copepods in a given region at different times, and his conclusions bear on the movements and abundance of the food-fishes whose immediate or ultimate pabulum the copepods are. His paper is published in the Fish Commission Bulletin for 1901.

Prof R. W. Tower, of Brown University, conducted a number of chemical and physiological investigations addressed to the food-fishes of the region. An inquiry regarding the organic constituents of the scales of fish and their use in the manufacture of gelatin was conducted jointly by Professor Tower and Mr. E. H. Green, and a special report thereon was published in the 1901 Bulletin. Numerous gallstones were found in several of the squeteague caught in the pound nets, and the determination of the chemical constituents of the calculi formed the subject of a paper by Professor Tower and Mr. A. K. Krause, forming a part of the 1901 Bulletin, which is an important contribution to the diseases of wild fishes. A related subject which received attention was the bile pigments and bile acids of squeteague, blue-fish, and bonito.

In the course of a general study of noises produced by fishes, some important physiological observations were made on the "drumming" of the squeteague. The drumming of the drum-fishes (*Scienidie*), of which the squeteague is the most prominent representative at Woods Hole, has been variously explained by different writers; and in the case of the squeteague, at least, it would appear that no accurate account of the factors producing the characteristic sound has heretofore been given.

Professor Tower's observations and experiments have developed the following facts:

1. There is in the squeteague a special drumming muscle, lying between the abdominal muscles and the peritoneum, and extending the entire length of the abdomen on either side of the median line.

2. The muscle fibers are very short, and run at right angles to the long axis of the muscle.

3. The muscle is in close relation with the large swim-bladder, and by its rapid contractions produces a drumming sound, with the aid of the tense bladder which acts as a sounding-board.

4. This muscle exists only in the males, and only the males are able to drum.

In continuation of the plan of issuing from time to time systematic reports on the various groups of water animals in the Woods Hole region, studies of the following groups were carried on during the year: The crabs, by Dr. Robert P. Bigelow, of the Massachusetts Institute of Technology; the jelly-fishes and sea-anemones, by Prof. Charles W. Hargitt, of Syracuse University; the parasitic copepods of fishes, by Mr. M. T. Thompson, of Brown University, and Mr. C. B. Wilson, of the Westfield (Massachusetts) State Normal School; the isopods, by Miss Harriet Richardson, of Columbian University (Washington, D. C.); the amphipods, by Prof. S. J. Holmes, of the University of Michigan

Following is a list of those in attendance at the laboratory, arranged under the institutions with which they were connected:

U. S. Department of Agriculture: W. T. Swingle, Ph. D.; Dr. Geo. T. Moore; Karl Kellerman, B. S.

Brown University. R. W. Tower, A. M.; L. W. Williams, Ph. D.; George H. Sherwood, A. M.; M. T. Thompson, A. M.; A. K. Krause, A. B.

Bryn Mawr College: T H. Morgan, Ph. D.

Cotumbia University. Gary N. Calkins, Ph. D.

Harvard University: George S. Amsden, A. B.; Henry B. Bigelow, A. B.; J. H. Converse; Julius M. Johnson, A. B.; Clarence H. Lander, B. S.; F. T. Lewis, M. D.; James H. McMurray; Thomas Ordway, A. B.; George H. Parker; H. W. Rand, Ph. D.; M. E. Stickney, A. M.; R. M. Strong. Ph. D.; William A. Willard, A. M.; Robert M. Yerkes, A. M.

Indiana University: W. J. Moenkhaus, Ph. D.

Johns Hopkins University: Caswell Grave, Ph. D.; Henry F. Perkins, A. B.

Massachusetts Institute of Technology: Robert P. Bigelow, Ph. D.; Erik H. Green, A. M.

College of City of New York: Francis B. Sumner, Ph. D.

Princeton University: Ulric Dahlgren, Ph. D.; C. F. Silvester.

Syracuse University: Charles W. Hargitt, Ph. D.

Yale University: W. G. Van Name, Ph. D.

Miscellaneous: John Barlow, A. M., Fairmont College, Wichita, Kans.; E. W. Barnes, Tabor College, Iowa; W. B. Bell, University of Iowa; W. A. Denny, A. M., Anderson (Ind.) High School; Otto Folin, Ph. D., McLean Hospital, Waverly, Mass.; Henry R. Linville, Ph. D., De Witt Clinton High School, New York City; Porter E. Sargent, A. M., Browne & Nichols School, Cambridge, Mass.

BEAUFORT, NORTH CAROLINA (H. V. WILSON, DIRECTOR).

The Fish Commission laboratory at this place was in operation at the beginning of the fiscal year and remained open until September 25, the same temporary quarters being occupied as in previous years. Prof. H. V. Wilson, of the University of North Carolina, continued in charge. A dwelling-house near the laboratory was rented for a dormitory and mess-house. The launch *Petrel* was attached to the station during the season and was in constant use. About 20 persons availed themselves of the privilege of working at the laboratory; these, with the institutions with which they were connected, were as follows:

Johns Hopkins University: Prof. W. K. Brooks, Dr. Caswell Grave, Messrs. R. P. Cowles, D. H. Tennent, O. C. Glaser, R. E. Coker, and J. A. E. Eyster. Columbia University: Prof. E. B. Wilson, Messrs. H. B. and J. C. Torrey. University of North Carolina: Prof. H. V. Wilson and Mr. C. A. Shore. University of Missouri: Prof. George Lefevre and Dr. W. C. Curtis.

Washington and Jefferson College: Prof. Edwin Linton and Mr. C. W. Stone.

University of Alabama: Dr. J. Y. Graham.

Bryn Mawr College: Prof. T. H. Morgan.

Dartmouth College: Dr. J. H. Gerould.

Professor Brooks studied the eggs of the oyster and preserved material for further work on the same. Prof. E. B. Wilson was engaged in experimental studies of the living eggs of the sea-urchin, *Toxopneustes*, and Professor Morgan worked on the eggs and larve of the same species in connection with his researches on regeneration. Professor Linton began a systematic examination of the food-fishes of the Beaufort region with reference to their parasites. Professor Graham studied a trematode worm which is parasitic in the oyster.

Dr. Grave, assisted by Mr. Glaser, continued the work on the biology of the North Carolina oyster and conducted experiments with a view to develop a method by which oyster-farming may be successfully carried on in the North Carolina sounds, where, on account of the peculiarity of the bottom in many places, the ordinary methods of planting are inapplicable.

Mr. Coker investigated a barnacle (*Dichelaspis*) parasitie on the gills of the common edible crab. From a report submitted by Mr. Coker it appears that this parasite affects over 50 per cent of the male crabs and about 90 per cent of the females; that it is not found in young crabs, being thrown off by the frequent molting; that crabs whose gills are heavily burdened with the parasite have less vitality, are sluggish in their movements, and are the first to die in captivity. While the usual number of barnacles found in one crab is from 2 or 3 to 8 or 10, in some the gills are filled to overflowing and may contain 500 to 1,000 of the parasites.

The new laboratory buildings on Pivers Island were nearly completed by the end of the year, and on May 26 it was practicable to throw the laboratory proper open to investigators. Prof. H. V. Wilson, the director, having gone abroad, Dr. Caswell Grave, of Johns Hopkins University, was appointed to the position. The operations of the laboratory during the last few weeks of the fiscal year 1902 will be referred to in the report for the next year.

WORK IN FISH PATHOLOGY.

The occurrence of serious disease among fishes at the hatcheries of the Commission and elsewhere has required the almost constant attention of Mr. M. C. Marsh, the assistant assigned to this subject, and has shown the wisdom of making special provision for the study of this increasingly important branch.

A part of the summer and fall was spent by Mr. Marsh at the Northville (Michigan) station of the Commission in considering the disease affecting the brook trout. A bacterial organism was isolated from the dying fish and the disease was reproduced in healthy trout by inoculation. On the recommendation of this division, two ponds were constructed entirely of concrete and cement for the purpose of excluding disease-producing bacteria, and the ponds were stocked with healthy trout from the Au Sable River and from a private trout farm at Osceola, Wis. Mr. Marsh visited this farm to inspect the fry and yearling fish prior to securing a supply for Northville. The large spring pond constituting the main water supply was drawn down, cleaned, and thoroughly disinfected with chlorinated lime. Pathological material and cultures were brought to the Washington laboratory, and a study of the the offending organism was taken up. This germ can not be identified with any hitherto-known species, and a full description of its form and behavior is substantially completed.

At the meeting of the American Fisheries Society, held at Milwaukee, Wis., in July, Mr. Marsh brought the brook-trout disease to the attention of the assembled fish-culturists.

An investigation of the mortality among brook trout at the Paris station of the Michigan Fish Commission disclosed the same disease as at Northville, but in a milder form. Mr. Marsh visited by request the hatchery of the Pere Marquette Club at Wingleton, Mich., where brook trout were found to be slowly dying of the Northville disease, and some suggestions for the amelioration of the conditions were made.

The existence of fungous disease among fishes in the Government aquaria at the Pan-American Exposition, as noted in the report for last year, continued during the summer and required attention. Experiments with potassium permanganate and formalin confirmed the previously expressed opinion that they had no advantages over common salt as a remedy for this troublesome disease.

In March a visit of about one week was made to the Charleston Exposition to look into some cases of mortality among aquarium fishes. No serious losses were occurring, and some previous trouble was probably due to polluted water from the lagoon from which the water supply was drawn. The brook trout were slowly dying and these were infected with the Northville organism, which makes an interesting addition to the recorded distribution of this species. Local fishes taken for the exposition were not in the best condition and this accounts partly for the aquarium losses. Both salt and fresh water supplies were rather peculiar and not of the best for aquarium purposes, the river water being subject to contamination from phosphate works and the fresh artesian water containing considerable soda, like all of the artesian water of the region.

MISCELLANEOUS LABORATORY WORK, REPORTS, ETC.

FISHES FROM THE PHILIPPINE ISLANDS.

The Commission received through the Surgeon-General of the Army specimens of fishes and fish cakes from medical officers in the Philippine Islands. The fish were from Lake Buhi, in southern Luzon, and represented five or six species, several of which were previously unknown. The most interesting and important of these was an exceedingly diminutive form, caught in large numbers by the natives and used for food. In forwarding specimens of these fish, Dr. George A. Zeller wrote as follows from the military hospital at Buhi:

I inclose herewith samples of a strange article of diet greatly relished by the Bicols, among whom I have been stationed for the past eighteen months. Rice and fish are the staple articles of diet for most Filipinos and in the provinces of the Camarines there is little variation from these two. Fishes of every size and many varieties are prepared in every conceivable form, but the samples inclosed are unique in that they are found here and nowhere else. * * * Many varieties of fish abound in the lake, but by far the most numerous are these minute specimens. They are called in the native Bicol tongue sinarapan, and when dried in the sun on a leaf are called *badi*. They are caught by a large sheet of close web, which is dipped under wherever a school congregates. They are put into tightly woven baskets from which the water soon drains, leaving a compact mass of fish. They are not minnows or immature fish. The natives buy them cagerly; and when the little fleet of fishermen return from their morning's quest and place their baskets upon the ground on the market place, they are instantly surrounded by a crowd of waiting children, who, armed with every sort of dish, are anxious to take home the family

meal. They bring three or four potatoes, tubers, a handful or two of rice, or a few copper pennics, and in exchange receive about a pint of fish. In the kitchen the fish are made up with peppers or other spiced herbs, and they do not taste bad. The soldiers have become quite fond of this food, and liberally patronize the little native restaurants where it is served.

This fish proved to be of an undescribed genus and species, and its diagnostic features were given in an article in Science (January 3, 1902), where the name *Mistichthys luzonensis* was applied to it. The maximum length of the species is only 0.6 inch and the average slightly over 0.5 inch. It is the smallest known fish and probably the smallest known vertebrate.

Through the courtesy of the Surgeon-General of the Army, the Commission was enabled to place three collecting outfits in the hands of medical officers located in various parts of the archipelago, and it is expected that additional specimens of interest will thus be obtained.

SHAD OF THE OHIO RIVER.

Prof. B. W. Evermann concluded his study of the shad of the Ohio River, referred to in the annual report for 1898, and submitted a paper thereon which was published in May, 1902. Publication of this article was delayed in the hope that opportunity might be afforded for obtaining further information on this fish, especially its migration from the Gulf of Mexico up the Mississippi and its tributaries.

This shad proves to be an indigenous species, and is not, as some have supposed, the transplanted shad from the Atlantic coast. It has appropriately been named *Alost chiensis*. It is an excellent food-fish, probably not inferior to the common shad, but is not highly regarded by the people of the Mississippi basin, the price received by fishermen being only 2 cents a pound. Its abundance and distribution are not yet known, and the annual eatch is quite small and localized.

FISHERIES OF THE GREAT LAKES, ST. LAWRENCE RIVER, AND LAKE CHAMPLAIN.

The extensive collections of fishes from these waters obtained by the Commission during a series of years have been reported on by Prof. Barton W. Evermann and Dr. W. C. Kendall, in four annotated lists published in March and April, 1902. The number of species and subspecies known from the Great Lakes and their tributary waters is 152, of which 27 are peculiar to Great Lakes basin. From Lake Ontario 73 species are recorded, and from the St. Lawrence River 71. The fish fauna of Lake Champlain includes 54 species:

SILVERSIDES OF THE EAST COAST.

The silversides are among the most abundant of the small fishes inhabiting the salt, brackish, and fresh waters of the Eastern and Southern States. Their maximum length is but little over 6 inches, and most of them are hardly half so large; they are, therefore, only sparingly eaten by man, but they constitute one of the most important

foods for many of the best food-fishes of the coast. Extensive collections of the Fish Commission, supplemented by material in the National Museum, were studied by Dr. W. C. Kendall, and a report^{*a*} thereon was issued in April, 1902. In this paper the abundance, uses, habits, food, etc., of the silversides are considered, and a detailed description, with figure, of each species is given.

FISHES OF MEXICO.

Recent collections of fishes from various parts of Mexico, obtained by the Division of Biological Survey of the U. S. Department of Agriculture, have been referred to this Commission for identification, and have been reported on by Messrs. B. W. Evermann and E. L. Goldsborough in a paper issued May 3, 1902. These collections, supplemented by several smaller ones from various sources, comprised 56 species, of which 5 were previously undescribed.

FISHES OF LABRADOR.

At the request of Prof. Leslie A. Lee, of Bowdoin College, Maine, Dr. W. C. Kendall identified and reported on a small collection of fishes obtained on the Labrador expedition of that college in 1901. The report will form one of a series of articles on the natural history collections of that expedition. Professor Lee donated to the Commission specimens of all the desirable duplicates.

a Notes on the Silversides of the genus Menidia of the East Coast of the United States, with descriptions of two new subspecies.

REPORT OF THE DIVISION OF STATISTICS AND METHODS OF THE FISHERIES.

BY C. H. TOWNSEND, Assistant in Charge.

The commercial fisheries of the United States employ about 200,000 persons, the amount of capital invested is \$60,000,000, and the annual value of the products to the fishermen is approximately \$50,000,000. The different regions in which fisheries exist are the New England, Middle Atlantic, and South Atlantic States on the Atlantic coast, the Gulf States on the Gulf of Mexico, the Pacific coast States, Alaska, the Great Lakes, and the various rivers and minor lakes.

At the commencement of the present fiscal year the statistical agents of this division were in the field engaged in investigations of the lobster, sturgeon, menhaden, and salmon fisheries of the Atlantic coast. A thorough canvass was made of the entire lobster fishery, Mr. W. A. Wilcox canvassing Massachusetts; Mr. T. M. Cogswell, Massachusetts and New Hampshire; Mr. E. S. King, Rhode Island; Mr. C. H. Stevenson, New York; Mr. W. A. Roberts, Connecticut and a portion of Rhode Island; Mr. John B. Wilson, New Jersey and Delaware; Mr. G. H. H. Moore, Maine. Mr. C. G. Atkins, superintendent of the Fish Commission station at Craig Brook, Maine, made a canvass of the salmon fishery of the Penobscot River. Mr. J. N. Cobb, who during the summer had been detailed to assist in an investigation of the fisheries of the Hawaiian Islands, was for a short time engaged in making inquiries respecting certain fisheries centered in New York City. In the autumn Mr. C. H. Stevenson made inquiries in Connecticut and Massachusetts respecting the preservation of fishery products. Mr. E. A. Tulian, superintendent of the Fish Commission station at Leadville, Colo., made a canvass of the fisheries of Utah and Colorado.

A canvass of the fisheries of the Middle Atlantic States was then begun, Mr. W. A. Wilcox taking up the work in Virginia and Mr. J. B. Wilson in New Jersey. Mr. Roberts was assigned to the canvass of Maryland and was assisted for a time by Mr. Wilson, who later took up the work in New Jersey. Mr. Cobb was assigned to New York and Mr. Stevenson to portions of Virginia and Maryland. Mr. Thomas B. Gould was temporarily employed in canvassing the fisheries of Pennsylvania and New Jersey on the Delaware River. At the close of the fiscal year the investigations of the fisheries of the Middle Atlantic States were still in progress.

Mr. Townsend, assistant in charge, after representing the Commission at a meeting of the American Fisheries Society at Milwaukee, Wis., in July, made a reconnaissance of the fisheries of the Great Lakes west of Lake Ontario. In June he accompanied the Assistant Secretary of State to The Hague in connection with the arbitration of American whaling and scaling claims against Russia.

Capt. S. J. Martin and Mr. F. F. Dimick, statistical agents of the division located at Boston and Gloucester, Mass., have continued to submit their monthly reports on the quantity and value of certain fishery products landed at those ports by American vessels.

Mr. A. B. Alexander, of the steamer *Albatross*, was employed for a short time in making inquiries relative to the increase, among commercial fishermen, of hook-and-line fishing for salmon at Monterey, Cal., and elsewhere on the Pacific coast.

The following bulletins, issued as single sheets, containing advance statistics in condensed form, were widely distributed during the year:

114. Lobster fishery of the United States, 1900.

117. Statement of the quantity and value of certain fishery products landed at Boston and Gloucester, Mass., by American fishing vessels during the year 1901.

Other bulletins, showing the quantity and value of fishery products landed at Boston and Gloucester, have been issued monthly as usual.

The publications appearing during the year which were prepared in this division were:

Records and bibliography of the steamship *Albatross*, by C. H. Townsend. Statistics of the fisheries of the Great Lakes. Notes on the fisheries of the Pacific coast, by W. A. Wilcox (in press).

BOSTON AND GLOUCESTER.

The local agents of the Commission at Boston and Gloucester have continued to make monthly reports on the great fisheries centering there. The total quantity of products landed by American vessels during the year 1901 was 151,165,191 pounds, worth \$4,245,951. These figures as compared with those for the previous year are somewhat smaller, there being a decrease of 11,053,730 pounds and a decrease in value of \$139,151. The total number of fares landed was 6,964, a decrease of 549 as compared with the year 1900.

The fish landed at Gloucester amounted to 92,173,060 pounds, valued at \$2,674,551, a moderate decrease in both quantity and value from the previous year. The decrease is shown in the quantity of fresh fish landed, the amount of fish salted being somewhat larger. The fares landed at Gloucester numbered 3,561, of which 2,899 were from grounds off the New England coast and 662 from the Eastern Banks. The total of fish from grounds off the New England coast was 34,835,456 pounds, worth \$1,050,211. The quantity from the Eastern Banks was much larger, amounting to 57,337,604 pounds, worth \$1,624,340.

At Boston the decrease amounted to 7,828,781 pounds and \$27,106in value. The fares landed at Boston were 3,403,170 being from the Eastern Banks and 3,233 from grounds off the New England coast. At this port the greater quantity of the fish was derived from grounds off the New England coast. The total quantity of products landed at Boston was 58,992,131 pounds, worth \$1,571,400, the fresh fish amounting to 56,855,111 pounds, the salt fish being only 2,137,020 pounds. It should be noted that at Gloucester the quantity of salt fish is greatly in excess of that landed in a fresh condition.

FISHERIES OF UTAH.

The fisheries of Utah in 1900 employed 505 persons, most of whom fished in Utah Lake. The capital invested was \$52,985; \$33,400 of this amount is credited to Utah County. Seines and hand lines constituted the principal forms of apparatus in use. The products amounted to 1,081,863 pounds, valued at \$47,458. By far the greater part of the catch was derived from Utah Lake, in Utah County. Weber, Rich, and Garfield counties are next in regard to the quantity of fish taken. The principal species taken were, carp, 353,885 pounds, valued at \$4,494; trout, 145,798 pounds, \$24,678; black bass, 104,800 pounds, \$11,105; suckers and mullet, 452,780 pounds, \$4,833.

Mr. E. A. Tulian reports that black bass, carp, trout, and bullheads have greatly increased in Utah County since 1895. The bass, carp, and bullheads were nearly all taken in Utah Lake and its tributaries. Bass weighing 7 to 8 pounds are sometimes taken, and are said to be of excellent quality. The bullheads introduced into the lake four or five years ago are increasing and find a ready sale at good prices. The black bass and carp are also introduced species.

It appears that an important quantity of fish is taken and sold contrary to law, so that the yield of fish from the waters of Utah is larger than the present figures show.

Most persons engaged in fishing in these waters carry on the business in a desultory manner. Considerable quantities of fish are taken by farmers living in the vicinity of Utah Lake, many of them spearing carp in the winter time for their own use.

CARP.

The wholesale trade in carp in New York City.—During the progress of the canvass of the fisheries of New York City for the year 1901 Mr. Cobb made inquiries respecting the trade in German carp. The item of carp in the fish supply of the city is quite important, amounting to 6,906,950 pounds, valued in New York at \$197,451. While small quantities are received incidentally by most dealers, the handling of the greater part of the supply is done by a few firms only.

Carp in the New York markets are mainly from the Illinois River and from Lake Erie, the balance coming generally from eastern points, notably East Bay, L. I., the Delaware River, Havre de Grace, Md., and Washington, D. C. Most of the carp are received from April to September, inclusive, the remainder arriving in the winter months. Hebrew retail dealers and peddlers dispose of the greater part on the East Side, some going to Philadelphia and to points in New England. As the Hudson River contains many carp, it is probable that New York will in time be supplied with cheap fish from that source.

The following table shows the quantity and value of German carp handled in the wholesale markets of New York City during 1901:

| Seasons. | Lbs. | Value to fishermen. | Value to dealers. |
|--|----------------------|---|--|
| Jan, 1 to Mar, 1. Mar, 1 to Apr, 15. Apr, 15 to June 16. June 16 to Sept. 1. Sept. 1 to Dec. 1. Dec. 1 to Jan, 1. Total for the year | 589,500 2,040,000 | \$10, 649 7, 370 20, 040 29, 700 51, 813 13, 163 132, 735 | \$17, 748 11, 790 34, 000 44, 550 71, 138 18, 225 197, 451 |

The above values represent the selling price in New York. The value of this quantity of carp to the fishermen was \$132,735, which does not include freight or express charges.

The carp trade in general.—The carp industry of the Illinois River has been important for several years, the catch in 1901 amounting to $5,780,200^a$ pounds, valued at \$173,406. The catch in Lake Erie in 1900 was 4,598,090 pounds. The quantity marketed in the United States is, according to the latest statistics available, 17,160,873 pounds, valued at \$407,633. As the figures for some sections of the country are over three years old, and as the consumption of carp is increasing, the quantity put on the market annually is probably over 20,000,000 pounds.

Where dealers have worked up regular markets for carp, and handled them in quantities large enough for profit at the low prices obtained, hopeful opinions will be heard; where these fish are received incidentally they can not be handled with profit, and opinions just the reverse will be expressed regarding their presence in the fish trade.

a Report of the Illinois Fishermen's Association for the year ending December 31, 1901.

HOOK-AND-LINE FISHING FOR PACIFIC SALMON.

Mr. A. B. Alexander, of the steamer *Albatross*, has furnished some interesting notes relative to the taking of Pacific salmon with hook and line.

Trolling for salmon in Monterey Bay has increased steadily each year since its beginning, and in 1901 there were taken by this method, approximately, 190,786 pounds of salmon, or about 10,000 fish in number, most of which was placed in cold storage and shipped to various Eastern markets. About 100 boats were engaged in the fishing.

Previous to 1893 few salmon were taken in Monterey Bay by any kind of apparatus. In that year trolling for them was found to be very successful and the discovery was quickly taken advantage of by anglers and commercial fishermen. It was not known that salmon could be taken with the hook in this bay in paying quantities, the reason being, doubtless, that the fish do not appear leaping at the surface, as is the custom when entering fresh water. Most of the fishing is done in the summer time, but a moderate number of fish can also be taken in Monterey Bay during the winter months.

The fish appear in numbers about the first week in June, when the sardines are most numerous. The salmon are also found feeding on smelts and squid. The fish are taken in two ways, by trolling with the spoon with and without bait, and with the baited hook used at a considerable depth with a heavy sinker. Previous to the arrival of the sardines and other species on which the salmon feed the fishing is done mostly by trolling with the rod and spoon, but as soon as bait is to be had this method is abandoned for the sinker and hook. As a substitute for bait the baited spoon is sometimes used, but the baited hook is preferred by the commercial fishermen.

Sportsmen who visit the bay from San Francisco and elsewhere use split bamboo rods ranging from 10 to 12 ounces. Both silk and linen lines are employed, varying in length from 150 to 200 yards. The spoons vary in size from Nos. 5 to 7. The average hook used in connection with the spoon corresponds in size to the No. 14 cod trawl hook, with a slightly longer shank. Some fishermen use the brazed treble hook, but it is not a favorite with sportsmen. All the fishing is carried on from skiffs and small rowboats.

As the numerous commercial fishermen do not often use a spoon, many more salmon are taken with baited hooks. A common bamboo pole is used by the fishermen, with a cotton line of 32 thread, from 80 to 100 feet in length. The hook is 5 inches long and shaped like a halibut hook, with a longer shank. In baiting the hook care is taken to have the shank entirely covered, leaving the barb and point bare. The sinker is quite heavy, being about 4 pounds in weight and fastened to the line 25 feet above the hook. When the salmon is hooked the pole is dropped and the line is hauled in hand over hand, great care being taken that the fish does not break away. Frequently the fishing is done without the use of the rod. When the sinker is used the trolling is done at a depth of at least 20 feet. The usual sailing speed in trolling is 4 miles an hour, and the average size of the salmon taken is a little over 20 pounds, although 50-pounders are sometimes caught. The best fishing is usually to be had during the afternoon, and 25 fish are considered a good day's catch for one hook.

Monterey is the most southerly point where salmon are taken, either commercially or for sport. Very few salmon are taken with the hook in San Francisco Bay and the Sacramento River. In the Eel River there is good salmon trolling to be had in the fall. The fish are taken in tide water chiefly by professional fishermen, using from 20 to 30 boats, but many anglers visit these waters for the sport fishing. It takes the angler an hour on an average to land one of the larger fish. Similar fishing is done by anglers in a number of the smaller coast rivers, such as the Russian and Nevarro, the Olema, and about the head of Tomales Bay. Steelhead salmon are frequently taken in these waters with artificial flies.

The Indians of Neah Bay, Washington, do considerable trolling for silver salmon and have been known to take as many as 4,000 fish in a day. The principal fishing-grounds lie off the mouth of the bay and in the vicinity of Tatoosh rock off the coast and some 2 or 3 miles farther south. The catch is usually disposed of at Port Townsend. The Indians repair to the grounds early in the morning, remaining out all day and sometimes after dark if the weather permits. The spoons employed are larger than those used elsewhere on the coast. The lines are usually of 30 thread and about 150 feet long. Pieces of salmon and small herring are used for bait. In trolling the canoe is paddled, except in very light breezes, when the sail is set.

Salmon trolling has long been practiced in Puget Souna, where sportsmen use the rod and reel.

At Killisnoo, Alaska, the king salmon take the spoon readily, the fish coming in to feed on the herring which annually visit these waters in great numbers. Spoons and lines of the same pattern as those used at Neah Bay are employed by the Killisnoo Indians. The same bait is used and the fish taken are for their own consumption.

When salmon will not readily take a spoon at the surface, a baited hook towed near the bottom frequently induces them to bite.

There can be no doubt that there are many other places along the west coast where salmon could be taken by trolling. They have recently been taken from vessels 10 or 12 miles off the coast of Washington, the bait being towed at 30 fathoms where the soundings were 40 fathoms. It now seems probable that a thorough trial by deep trolling all along the west coast will show that the salmon are "on soundings" and not far from the coast during most of the time they spend at sea.

THE LOBSTER FISHERY.

During the summer of 1901 a canvass was made of the entire lobster fishery of the Atlantic coast of the United States. The number of persons engaged this fishery was 4,348, including 4,059 fishermen and 289 shoresmen. There were 191 vessels employed, aggregating 1,888 tons, valued with their outfits at \$216,674. The boats in use, with launches and steam vessels under 5 tons, numbered 3,960, and were valued at \$261,918. There were 208,563 lobster pots employed, worth \$224,111. Shore and accessory property was valued at \$454,457, and the cash capital amounted to \$510,900. The total investment in the fishery was \$1,668,060; of this amount \$960,529 is credited to Maine, \$570,923 to Massachusetts, \$54,516 to Rhode Island, \$59,133 to Connecticut, \$14,589 to New York, \$5,960 to New Hampshire, \$2,320 to New Jersey, and \$90 to Delaware.

The total yield of the fishery was 15,767,741 pounds, with a first value of \$1,390,579. The yield is credited to the States as follows: Maine, 12,346,450 pounds, worth \$1,062,206; Massachusetts, 1,805,042 pounds, \$171,825; Rhode Island, 660,017 pounds, \$58,026; Connecticut, 550,450 pounds, \$51,484; New York, 156,260 pounds, \$21,224; New Hampshire, 205,122 pounds, \$19,078; New Jersey, 40,800 pounds, \$6,400; and Delaware, 3,600 pounds, \$336.

YIELD AND VALUE OF LOBSTERS IN VARIOUS YEARS.

The following table showing the yield and value of the lobster fishery in former years is compiled from the reports of the U. S. Fish Commission, and shows the yield and value of lobsters in each of the lobster-producing States on the Atlantic coast in all years for which the fishery has been investigated from 1880 to 1898. No lobsters were reported for Delaware in 1880, but, with this exception, the omission of statistics for any of the States in any of the years enumerated is due to the fishery not being canvassed. The total yield of lobsters for all the States in 1880 was 20,128,033 pounds, value \$483,891; in 1887, 28,882,180 pounds, value \$799,717; in 1888, 28,108,970 pounds, value \$836,617, and in 1889, 30,771,573 pounds, value \$861,297. Complete totals can not be shown for other years because the fishery was not investigated in all the States. The total yield in 1892, omitting New York, was 23,559,432 pounds, value \$1,046,647; and in 1898, omitting Delaware, it was 15,118,062 pounds, value \$1,318,299.

NOTES ON THE LONDON FUR-SEAL TRADE.

While en route to The Hague, where he was detailed in connection with the arbitration of whaling and sealing claims against Russia, Mr. Townsend made inquiries in London respecting the trade in fur-seal skins, which has long been centered there.

The prices of fur-seal skins have been subject to considerable fluctuation for several years, owing to the effect of pelagic sealing in Bering Sea and the North Pacific Ocean on the sealing industries of the Pribilof and Commander islands. Frequently the majority of the seal skins on the market has consisted of the low-grade skins yielded by the pelagic fisheries.

The following table, showing the numbers and values of salted furseal skins from all sources placed on the London market during the period from 1871 to 1901, was procured from Messrs. C. M. Lampson & Co., of London. It is interesting chiefly on account of comparisons presented between the prices of the miscellaneous skins resulting from the wasteful pelagic scaling, and those of scals taken under the best The classification of the skins is that customarily used in conditions. the fur trade. The numbers indicate the catch of salted skins received from each source, not the yearly sales, as in some cases catches are not all sold during the years in which they were taken.

4.11Besides the above, data exist as follows: Robben Island, 1886, 1,832 skins at \$7.87; Galapagos, 1886, 993 skins at \$1.70; 1887, 99 skins at \$1.46. Sundry sources: 1887, 239 skins at \$4.14; 1809, 64 skins at \$0.44.

a Figures for August not obtained.

b Not yet all sold.

The sources from which fur seals are derived are as follows: The skins known to the trade as "Alaskas" are those of surplus male seals killed on the Pribilof Islands, under United States government supervision; "Copper" and "Robben Island" are similar in character, and are killed on the Commander and Robben islands, respectively, under direction of officers of the Russian Government; "Lobos" skins are those derived from the Lobos Islands in the mouth of the Rio de la Plata, and are killed under supervision of the Government of Uruguay. The term "Northwest coast" is used to designate the entire pelagic catch of the North Pacific Ocean and Bering Sea. Skins known as "Cape Horn," "Cape of Good Hope," "Australasian," "Galapagos," and "South Sea" are the result of irregular sealing in all of these regions, seals being killed indiscriminately on their breeding-grounds. "Unalaska" skins are those of young seals of the year, commonly known as "Gray Pups," and are killed by natives, in the passes of the Aleutian Islands during their first southward migration.

THE SPONGE FISHERY OF FLORIDA IN 1900.

BY

JOHN N. COBB,

Agent of the United States Fish Commission.

F. C. 1902-11

BRINGING SPONGES FROM THE VESSELS TO SPONGE WHARF AT KEY WEST.

A SPONGE AUCTION AT ANCLOTE.

THE SPONGE FISHERY OF FLORIDA IN 1900.

By JOHN N. COBB,

Agent of the United States Fish Commission.

In 1901 the writer was detailed to make an investigation of the commercial aspects of the fishery, and the following notes give complete data showing its condition in the calendar year 1900:

GROUNDS, VESSELS, METHODS OF THE FISHERY, ETC. a

There are two well-defined areas of the Florida coast in which sponging is prosecuted.

A chain of "keys," or islands, starts from the mainland at about Miami, on the east coast, and extends, in the shape of a horn, far into the Gulf of Mexico, the Dry Tortugas being the westernmost point of the horn. In the waters surrounding most of these keys, and also between the keys and the mainland as far as Cape Sable, sponges are found. This is called the "key grounds" and is worked exclusively by spongers from Key West and the few inhabitants of the many keys. The earliest sponging was on these grounds.

The "bay grounds," which are the most prolific, are on the west coast, in the Gulf of Mexico, and extend from Johns Pass, a few miles north of the entrance to Tampa Bay, to St. Mark's light-house, a distance of about 200 miles. Sponges are also found in the Gulf between Tampa Bay and Cape Sable, but not in sufficient quantities to justify making trips specially to this region.

The sponges taken from these grounds are classified as follows by the spongers and buyers: Sheepswool, yellow, grass, velvet or boat, and glove. A few other unimportant kinds, such as "wire," "hardhead," etc., are generally included with those previously mentioned.

Vessels of a schooner or sloop rig, ranging from 5 to 46 tons (averaging slightly over 11 tons), operate chiefly on the "bay grounds," while small sloops, usually of less than 5 tons burden, work mainly on the "key grounds." The larger vessels, which average about \$1,168

a No effort has been made to give these subjects in detail, as they have been covered in other reports, to which the reader is referred as follows: The Fisherics and Fishery Industries of the United States. Tenth Census of the United States. The Fish and Fisherics of the Coastal Waters of Florida. Rep. U. S. Fish Com. 1987, pp. 225-342. The Florida Commercial Sponges. By Hugh M. Smith. Buill. U. S. Fish Com. 1987, pp. 225-240.

¹⁹ pls. Notes on the Florida Sponge Fishery in 1899. By Hugh M. Smith. Bull, U. S. Fish Com. 1899, pp.

in value, exclusive of outfit, carry from 5 to 13 men, while the smaller vessels, which average in value about \$780, including outfit, carry crews of from 3 to 5 men.

The larger Key West vessels make three to four trips per year to the "bay grounds," and some of them make one or two trips to the "key grounds." Each "bay" trip occupies about two months, while the "key" trip is made in about a month. The Tarpon Springs and Apalachicola vessels average about five trips each year, each trip occupying about two months. None of these latter vessels visits the "key grounds."

The "bay" trips are usually arranged as follows:

The first trip begins about the first week of January, and ends from the 10th to the 20th of March, the spongers working from the mouth of Anclote River to St. Martins Reef, about 40 miles. Many of the vessels do not make this trip, as the weather is usually cold and windy.

The second trip begins about April 1 and ends from the 10th to the 20th of June. The grounds between Johns Pass and Cedar Key are visited during this trip.

The next trip begins about July 1 and ends from the middle of August to the 1st of September, and is also carried on between Johns Pass and Cedar Key. This is usually the best trip of the year.

The fourth trip is called the "hurricane trip," from the fact that it is prosecuted during the hurricane season, and lasts from the middle of August to about the 10th of October, the same grounds being visited as on the two previous trips.

The last trip usually begins the early part of November and ends December 20, the Rock Island grounds being visited.

A number of the vessels refit previous to the last trip, while others wait until the first two months of the year for this purpose.

The crews work on shares. The owner, or "outfitter," furnishes the food, fuel, boats, apparatus, etc., for the trip. While sponging in the "bay" each member of the crew is assessed 35 cents per trip for watchman's fee at the "kraals," and 50 cents per trip for wood. After deducting these two items from the gross proceeds of the trip, the vessel takes half of the remainder, and the other half is divided up equally among the crew. Besides his regular share with the crew, the captain gets 10 per cent of the vessel's share, and each "hooker" gets one-fourth of one share from the vessel's portion. Should the captain also be a "hooker," which is generally the case, he only gets his regular 10 per cent.

The same division of proceeds is followed on the "key" trips, except that there are no charges for watchmen and for wood. The men generally camp on the keys where wood and water are convenient, and as settlers are scarce in this region the "kraals" do not have to be guarded.

The only apparatus used in this fishery is the sponge hook, a threetoothed curved hook attached to poles of varying lengths, according to the depth of water in which the sponger is working, and the sponge glass—a common water bucket with the bottom knocked out and a pane of window glass substituted. The latter is used for seeing below the surface when the water is disturbed by ripples.

A sponge "kraal," or pen, is generally about 10 feet square, built of wattled stakes, and is placed in shallow water in the shelter of some key or island. Each vessel usually owns one, and for better protection from thieves, a number of them are congregated at some convenient place and a watchman employed to guard them. For a number of years many of the "bay" spongers had their kraals at the north end of Anclote Key. As these were exposed to the full force of the wind when blowing from certain directions, considerable loss was sustained on several occasions by the storms washing the sponges out of the kraals and carrying them out to sea. Owing to this the kraals were removed in 1890 to Baileys Bluff, on the mainland about 2 miles north of the mouth of Anclote River. In 1900 certain of the spongers became dissatisfied and established knaals at Sawyers, about half a mile nearer the Anclote River. The latter are sometimes called the "Cabbage kraals," from a large cabbage palm standing on the beach just opposite the kraals. At Baileys Bluff there are about 85 kraals. while at Sawyers there are about 40. A few kraals are also located at North Key, close to the town of Cedar Key. This was at one time a very important kraaling place.

"Kraals" were also located at Rock Island and near St. Mark's light-house at various times.

The key spongers build their kraals at various places, no effort being made to keep them together, as in the "bay." The spongers usually select a convenient key and make their camp on shore, and build their kraal in some sheltered cove close to the shore. They suffer very little from thieves, so do not require watchmen. Should the key have any inhabitants, these usually watch over the kraal.

When first brought to the surface the sponges are black and slimy. As soon as a dingy has secured a load it is sculled to the vessel, unless the latter is too far away, when she sails down to the boat, and the load is transferred to the deck of the vessel. They are then spread carefully over the deck in their natural upright position so as to allow the slimy matter, or "gurry," to run off easily. At first they have a strong annoniacal smell, exceedingly disagreeable to those unaccustured to it; but this is soon succeeded by a scent very similar to that of decaying seaweed. After several days' exposure on the deck the sponges die and a good part of the "gurry" runs off. In the "bay" the vessels usually return to the kraals every Friday. The sponges are then transferred from the vessel to the kraal; where they are allowed to soak until the vessel returns from the next week's trip. Those brought in the previous week are then beaten out with a short, heavy stick, which removes most of the slime and animal matter still

remaining in them, while those to which the black scum still adheres are scraped with a knife. The sponges are then squeezed out quite thoroughly with the hands, after which they are removed to the shore and strung on pieces of coarse twine about 6 feet in length, in which shape they are ready for sale. All sponges are sold by auction.

SPONGES GATHERED IN FOREIGN WATERS.

In September, 1900, the schooner Serafina C., of Key West, made a trip to the Mosquito Coast of Nicaragua, and brought back about 1,016 pounds of sheepswool sponges and 44 pounds of velvet sponges. Most of these were taken in water shallow enough to permit of the sponges being secured by wading. No effort was made to gather other kinds, as they would not have sold for enough to pay for the collecting. The sheepswool and velvet sponges were of an inferior grade. On landing the sponges at Key West they were compelled to pay duty on them. Owing to the success of the Scrafina C. several other vessels have since been working on these grounds. For some years past Key West vessels have made occasional visits to these grounds, the schooner Sea Gull having been wrecked while returning from such a trip in 1886.

Shortly after the close of the Spanish war one or two of the vessels visited Cuba and brought back a few sponges. These were not gathered by the crew, however, but were purchased from the natives. As they were of an inferior grade, and duty had to be paid upon them, no effort was made to continue the business.

PREVIOUS ABUNDANCE.

The four tables given below show for a series of years the catch of the sponge fleet by places, by kinds, the average price per pound, and the relative importance of the different kinds in percentages of the total quantity and value of the erop. In these the overwhelming preponderance of Key West is very evident. Cedar Key and St. Marks have dropped out of the fishery entirely, while Tarpon Springs and Apalachicola have decreased slightly since 1897 so far as the quantity is concerned. The catch for 1900, in both quantity and value, exceeded that for any other year for which figures are available. The catch of sheepswool sponges for 1900 is lower than for 1895, but higher than for the other years. The value of this kind has increased very much, however. The catch of yellow sponges increased nearly 90 per cent, while the catch of grass sponges has almost doubled since 1899.

In the table showing the average price per pound the most noticeable features are the great increases in value of the sheepswool and the yellow sponges. While the sheepswool has been steadily increasing in value for years, the yellow suddenly jumped from 29 cents per pound in 1899 to 59 cents in 1900, which is the highest ever known. In 1901 they soared even higher yet, some lots being sold on the Key West sponge wharf for an average price of about \$1 per pound. This

SPONGERS AT WORK.

SPONGE YARD AT KEY WEST, SHOWING THE SPONGES DRYING.

increase is accounted for by the fact that the high prices prevailing for sheepswool sponges has caused many people to use yellow sponges in their stead for certain purposes. The general average for all kinds is also the highest for the period under question.

In the percentage table, while the average catch of sheepswool has been decreasing the average value has remained about the same. In 1900 the average value of yellow sponges is the highest of any previous year. The grass sponges show an increase in the average quantity over all other years, except 1897, which was an exceptional year for this kind.

IMPORTS AND EXPORTS OF SPONGES.

As the yield of domestic sponges is not equal to the demand, large quantities are imported each year, the greater part of these coming from the Bahama Islands, Cuba, Haiti, Greece, Austria-Hungary, and Turkey. During the fiscal year ending June 30, 1900, the imports of foreign sponges amounted in value to \$536,303, almost as much as the value of the catch of domestic sponges for the calendar year 1900, which was \$567,685. During 1900 we exported 71.642 pounds of domestic sponges, valued at \$32,199, most of which went to Great Britain, Germany, Netherlands, Belgium, and France. Most of these were grass sponges, for which there is very little demand in this We also exported \$84,100 worth of foreign sponges which country. had been previously imported. Except in the imports during 1900 there has been very little fluctuation during the last three years. The following table shows the imports and exports for the fiscal years 1896, 1897, 1898, 1899, and 1900:

Table showing the imports and exports of sponges in 1896, 1897, 1898, 1899, and 1900.

STATISTICS OF THE FISHERY.

The season of 1900 was one of the best that the spongers have had for years. Owing to the unusual clearness of the water on the "key grounds" the spongers were enabled to work over almost all the grounds, a thing which has not happened for some years. This was especially noticeable around Sandy Key, near Cape Sable. Usually vellow, muddy water is found stretching out for about 40 miles in every direction from this key, except toward the mainland, which is about 4 miles distant, and from a distance the surface looks like a light vellow mud bank exposed at low water after the mud has had time to dry. Last season was the first time in about fourteen years in which the spongers were enabled to work this section. A noticeable feature was the unusual number of rotten sponges gathered on this ground. No sign of this rot appeared on the surface of the sponge, but after it had been cleaned it could easily be seen by pulling aside the fiber at the bottom. In some of them the whole inside had been rotted away while the exterior presented a clean, healthy appearance.

The tables show the condition of the industry for 1900. The great preponderance of Key West is very noticeable in all of the tables, and this place leads in persons engaged in all branches of the business, with a total of 1,827 persons. Tarpon Springs is second, with 354.

An interesting table is the one showing the color and nationality of the persons engaged in the business. Among the spongers themselves the colored people predominate, there being 1,356 engaged, while the whites number 757. This disproportion is especially high at Key West. Among persons employed exclusively on shore the whites predominate, with 119 to 13 colored. Of 2,113 persons employed directly in sponging, 1,268 are British provincials, mostly from the Bahamas; of these, 1,013 are colored. The native-born Americans numbered 839, of whom 343 are colored. One Norwegian and 5 Portuguese are also engaged in the business. Among the shore employees the native-born Americans lead, with 114, of whom 13 are colored. The British provincials numbered 17, all white. There was also 1 Greek.

In the matter of vessels, boats, apparatus, and shore and accessory property, Key West far exceeds all the others combined, with a total investment of \$518,932. Tarpon Springs is second, with \$65,014, followed by Apalachicola, with \$10,652. The total investment for the fishery amounts to \$594,598. The Key West fleet shows a most gratifying increase since 1895. In the latter year there were 99 vessels of over 5 tons, and 185 vessels under 5 tons measurement hailing from this place, while in 1900 there were 136 vessels of over 5 tons and 183 vessels of under 5 tons measurement, a gain of 37 vessels of over 5 tons and a loss of 2 vessels under 5 tons. So far as vessels of over 5 tons are concerned, Tarpon Springs has practically held her own, while Apalachicola has dropped off considerably, but in the matter of vessels under 5 tons Tarpon Springs has made a considerable increase.

Key West leads in the catch of all kinds of sponges with 359,854 pounds, valued at \$488,744, followed by Tarpon Springs with 53,173 pounds, worth \$70,320, and Apalachicola with 5,098 pounds, valued at \$8,621. All the glove and velvet sponges were taken by Key West vessels. The total catch amounted to 418,125 pounds, valued at \$567,685.

An interesting feature is the showing of the catch by kinds and grounds. The "key grounds" were worked exclusively from Key West and the surrounding keys. The total eatch from the bay grounds amounted to 228,461 pounds, valued at \$389,890, and for the key grounds 189,664 pounds, worth \$177,795. Sheepswool sponges are more frequent on the "bay grounds" than on the key grounds, while the reverse is the case with yellow sponges. The grass-sponge catch is almost equally divided between the two grounds. Very few glove and velvet sponges are taken on the "bay grounds."

«Includes 1,016 pounds of sheepswool, valued at \$1,866, and 44 pounds of velvet, valued at \$34, from the Nicaraguan coast.

The following table shows the average price per pound received for each kind from the various grounds. The "bay" sheepswool are much more valuable than the "key" variety, while the "key" yellow, grass, and yelvet are all more valuable than those from the "bay." There is no difference in the value of the glove sponges from either ground. The general average price was \$1.36.

Heretofore the law in regard to the gathering of sponges less than 4 inches in diameter has been more honored in the breach than in the observance. This was largely owing to the fact that the law did not

prohibit the sale of such sponges or the having of them in possession. The law was amended in 1901 to cover these points, and will doubtless prove useful in protecting the small sponges from the depredations of the spongers, if properly enforced.

DISASTERS TO THE FLEET.

The spongers have not been exempt from the many perils of the deep, as is well shown by the following brief record of the principal disasters to the fleet since 1880:

| Year. | - Vessel. | Remarks. |
|-------|---|--|
| | Minnie | Struck on bar near Stump Pass. |
| 1886 | Sea Gull | Capsized by cyclone near Cuba while on her way back from sponging trip to Nicaragua; 7 lives lost, |
| 1892 | Ethel | Struck a drift log and foundered. |
| 1893 | Silver Spray | Burned. |
| 1894 | Adelaide | Capsized at Peckles Reef in gale. |
| 1895 | Marion, Rosalie, Euphemia, and Ada Norman. | |
| | Shamrock | |
| 1896 | Competitor | band goods to Cuban insurgents. Crew condemned to death, but saved through intervention of United States. |
| | Rosalie | Capsized during cyclone; 4 of her crew lost. |
| | Euphemia | Capsized in gale. |
| 1898 | Speedwell | Capsized near Marquas Keys. Had just been launched and was getting ready to go into sponging; 9 persons lost. |
| 1899 | Amanda Rosalie | Stranded during heavy blow. |
| 1900 | Vim | Beached. |
| | Evening Star | Struck on St. Martins Reef. |
| | Lone Star | |

SPONGE BUYING.

The buying of sponges gathered by the Florida fishermen has developed into a business of considerable magnitude and one quite distinct from that of the gathering of sponges.

When the sponges are landed by the fishermen they have merely been roughly cleaned of the mud and dirt adhering to them, and it is necessary, before they can be placed on the market, to thoroughly clean them of the remaining dirt, see that no foreign substances are inside the sponge, and trim off the rough edges to give a symmetrical appearance. This work is done by the buyers, who have large warehouses at convenient places on the coast.

For many years Key West had almost a monopoly of this business, but in 1891 serious competition began at Tarpon Springs. Owing to the favorable situation of this latter place the business here rapidly expanded until in 1900 it amounted to almost as much as at Key West. The Spanish-American war was a great help to Tarpon Springs, as the Key West vessel captains avoided going to Key West with their cargoes for fear of being captured by Spanish war vessels, and so were constrained to sell at Tarpon Springs. During 1899 and 1900 a few sponges were sold at Lemon City, on the east coast. Some of the "key" boats from the upper part of Biscayne Bay found it more convenient to sell to the one buyer there than to make the long trip to Key West. The business did not thrive, however, as the spongers do

not like to sell at a place where there is but one buyer, as they claim the lack of competition keeps the price down. None was sold at Lemon City after the spring of 1900.

At Key West and Tarpon Springs all of the buyers, except twoone at each place – represent New York, Philadelphia, and St. Louis wholesale houses. The two independent buyers market their own catch. Each buyer has a warehouse where the sponges are dried. cleaned, and baled ready for market. Some of these buildings are elaborate and costly structures, and a number of persons are employed at each in preparing the product. In 1900 the Key West establishments, which were valued at \$90,400, employed 67 persons, whose wages amounted to \$25,978. At Tarpon Springs, in the same year, the sponge establishments were valued at \$9,332, and gave employment to 57 persons, whose combined wages amounted to \$17,969. Property is much less valuable at Tarpon Springs than at Key West, which explains the great difference between the two places. The employees come under three classes, viz, "clippers," who clip the sponges and sort them; the "pressmen," who bale the sponges, and the draymen and common laborers. The "clippers" are paid about \$1.50 per day, the "pressmen" about \$2 per day, and the draymen and laborers about \$1 per day. At Key West very few buyers own drays, preferring to hire them when needed.

Burlap, which costs about 10 cents per yard, delivered, and jute rope, with diameters of one-fourth and three-eighths inch, worth about $7\frac{1}{2}$ cents, delivered, are used in baling the sponges. Formerly sisal rope was employed, but as it was found that jute rope could be secured at a much lower price, and would answer the purpose, the latter is now used almost exclusively.

In baling each kind is kept by itself. For the general trade sheepswool sponges are packed in 15, 30, and 50 pound bales. The mediumsize sponges are placed in the 15 and 30 pound bales and the large ones in the 50-pound bale. The yellow sponges are packed in 30, 40, and 50 pound bales; the medium size in the 30-pound bale, and the larger sizes in the 40 and 50 pound bales. The grass sponges are generally packed in 50-pound bales, while the velvet and glove sponges are packed in 30 and 50 pound bales. The above weights represent the net weight of the sponges in each bale. The burdap, rope, and twine usually adds about 2 pounds to the net weight of each bale. Bales weighing differently from the above are also put up, but only for special orders. In baling the sponges presses, very much resembling cotton compresses, are used. The serve wis purchased, but the framework is erected and the serve adjusted at the warehouse.

The great evil in the sponge business at the present time is the loading of sponges. Sheepswool sponges are nearly all loaded, while occasionally lots of yellow and grass sponges are also adulterated m this way. The loading is done for the purpose of increasing the

weight of the sponge. Rock salt, glucose, molasses, lead, gravel, sand, and stones are the substances generally used. Most of the warehouses have water-tight bins in which glucose or molasses, sand, and rock salt are mixed together in water. According as more or less weight is desired, the quantity of certain of the ingredients is increased or decreased. The sponges are thoroughly soaked in this preparation and are then run through an ordinary clothes-wringer, or laid on an inclined rack and allowed to drain into the bin. Some years ago the loading of sponges was quite common, and became such an evil in the trade that an agreement was made by the dealers that loading would be abandoned. This agreement was lived up to until within the last two or three years, when certain dealers resumed the practice. As the loading enabled the buyers to pay more for their sponges and still not increase the price to their customers, the buyers who had not taken it up were compelled to do so in self-defense. Most buyers would gladly abandon the loading if the agreement was made unanimous.

No sponges are bleached at the warehouses in Florida, this part of the business being done at the wholesale houses or by the jobbers in the trade. Small sheepswool sponges are quite generally bleached, as it gives them a better color. The bleaching of the vellow sponge, and the consequent great improvement in its hitherto poor color, has made it more attractive, and the increase in its value during the past year has been quite remarkable. Owing to the prevailing high prices for sheepswool, it is supplanting the latter for many purposes. In bleaching, lime and acids are used. This bleaching undoubtedly injures the sponges, as it weakens the fiber and considerably shortens the period of its usefulness. The spongers bleach a few sheepswool. They are usually washed in soapy water and, after being covered with soapsuds, are hung up on poles on shore or on the masts of the boats. The action of the nightly dews and the sunlight in conjunction with the soapsuds bleaches them to a beautiful white or golden color in one or two weeks. This manner of bleaching preserves the fiber of the sponge intact, and it is as durable when bleached as before. These sponges are either given away by the spongers or sold to the merchants in Key West, who sell them to tourists.

The two following tables show the condition of the sponge-buying business during 1900, and the rapid increase in the quantity of sponges bought at Tarpon Springs. In 1895 there were three buyers at this place and the total value of the sponges purchased amounted to \$60,000. In 1900 there were six buyers and their combined purchases amounted to \$278,550, an increase of three buyers and \$218,550 in value. In 1895 Key West had nine buyers, who purchased \$312,020 worth of sponges, while in 1900 there were eleven buyers, an increase of two, and the combined purchases amounted to \$289,135 in value, a decrease of \$31,865 in value. The decrease at Key West would

THE SPONGE FISHERY OF FLORIDA IN 1900.

undoubtedly have been greater had it not been for the exceptionally good catches on the "key grounds" during 1900. All the "key" sponges are sold at Key West and will likely continue so to be sold, as Tarpon Springs is too inaccessible for the "key" boats, but it is probable that in time most, if not all, of the sponges from the "bay grounds" will be marketed at Tarpon Springs. Over two-thirds of them were so disposed of in 1900. All of the data in the first table, except wages and buyings, have already been shown in the regular fishery tables.

AQUATIC PRODUCTS IN ARTS AND INDUSTRIES.

BY CHARLES H. STEVENSON.

PREFATORY NOTE.

The diversity and magnitude of the industries based on the utilization and manufacture of aquatic products are not fully appreciated. In a previous publication of this Commission " the great variety of fishery products used for food and their methods of preparation were discussed. In addition to the numerous items of food articles, the materials employed in the arts and industries compare favorably in variety and interest with similar products of the land. These may be roughly separated into five classes, viz, (1) oils, fats, and waxes; (2) fertilizers from aquatic products; (3) skins of aquatic animals and their products of furs and leathers; (4) the hard substances, as shells, scales, bones, ivories, etc., and (5) miscellaneous articles not properly classed with any of the foregoing, as glue, isinglass, seaweeds, sponges, marine salt, etc. The total value of the annual product of these throughout the world roughly approximates \$45,000,000 in the condition in which they are first placed on the market, of which the United States contributes \$11,000.000.

Some of the most extensive fisheries of the world have been prosecuted almost wholly for the purpose of supplying the oil markets. Whale oils were the first of all oils-animal or mineral-to achieve commercial importance, and for fully a century the whale fishery ranked as one of the principal industries of America. Indeed it was of far greater relative value in the industrial wealth of the country than the petroleum industries are at the present time. The seal fisheries of Newfoundland, Norway, and other northern countries, which rank among the most daring and venturesome of marine enterprises, are dependent for their prosperity on the oil obtained from the thick blubber underlying the skins of the animals. The taking of menhaden on the Atlantic coast of the United States for conversion into oil and fertilizer gives employment to thousands of men and to several million dollars of capital. And in the various cod fisheries of the world the rendering of the livers into oil for medicinal as well as for technical uses is a source of great profit. In addition to these extensive industries there are numerous minor fisheries supported entirely. or to a large extent, by the oil markets.

a The Preservation of Fishery Products for Food, Bulletin U. S. Fish Commission, 1898.

From all varieties of aquatic oils may be separated, at a low temperature, a solid fat or grease known as "foots" or "stearin," somewhat similar to the tallow obtained from sheep and oxen. This is obtained in the process of refining the oils, and the yield ranges from 3 to 20 per cent of the bulk of the crude oil. It is sold at a few cents per pound, and is used as a substitute for tallow from sheep and oxen in sizing yarns, as emollient in leather-dressing, and for various other technical purposes.

Bleaching the various marine oils produces a semi-solid fat known as "sperm soap," "whale soap," "menhaden soap," etc., according to the variety of oil treated. This material is used in smearing sheep, washing fruit trees, soap-manufacture, etc.

In the process of refining sperm oil, instead of the foots, the waxlike spermaceti is obtained, the quantity yielded approximating 11 per cent in weight of the crude sperm oil. Spermaceti is used principally in candle-making, as an ointment for medicinal purposes, for producing a polish on linen in laundering, and for self-lubricating cartridges.

Another wax-like substance peculiar to the sperm whale is ambergris, an extremely valuable substance found at rare intervals, but sometimes in comparatively large quantities within the intestines of that animal, and also afloat on the sea or cast up on the shores. A single whale has yielded \$50,000 worth of this material, and several intances are reported in which \$20,000 worth has been obtained from one cetacean. Ambergris was formerly used as an incense, in cookery, as a medicine, and as a perfume. Its principal use at present is in the preparation of fine perfumes.

The principal aquatic products used for fertilizer are seaweeds, shells of mollusks and crustaceans, non-edible species of fish, especially the menhaden, and waste parts of edible species. At present the quantity of this fertilizer produced annually in the United States alone approximates 420,000 tons, worth \$2,120,000. This is capable of very great increase, especially in the quantity of seaweeds and waste fish employed.

Doubtless 50 per cent of the world's stock of furs is obtained from aquatic animals. Formerly this percentage was greater, but it is reduced by the decrease in product of beaver, fur-seal, otter, and seaotter, and the large increase in quantity of certain land fur-bearers. Fully 75 per cent of all the furs produced in the United States are yielded by aquatic animals, principally the fur-seal, mink, muskrat, beaver, otter, and sea-otter. The value of the annual output of these in the United States approximates \$2,500,000 in the raw or undressed state.

Leather is made from the skins of practically all the aquatic mammals and of most of the species of fish, but these usually rank among novelty or fancy leathers. Seal leather is produced in large quantities, the value of the annual product averaging \$1,500,000. The hide of the beluga, or white whale, is one of the best of all skins for leather purposes, on account of its durability, strength, and pliability. It is sold as porpoise leather, and probably \$200,000 worth of tanned hides are marketed annually. Alligator skins are also obtained in large quantities, and owing to the peculiarity of their markings, are used entirely as fancy leather. Tanned walrus hides, especially the thick ones, are in great demand for polishing-wheels and other mechanical purposes, and about \$100,000 worth are sold annually. Among the aquatic skins used to a less extent for leather purposes may be mentioned sea-lion, porpoise, sea-elephant, and a very large variety of fish skins, especially those of sharks.

Of the hard substances existing in the form of shells, bones, scales, etc., shells are by far the most important. Nearly, if not quite, 1,000,000 tons are secured annually in the United States, consisting principally of the shells of oysters, clams, river mussels, and a very much smaller quantity of other varieties. A fair valuation of these at the places of consumption would doubtless amount to \$1,500,000; to this should be added about \$600,000 as the value of pearls secured during the last year in the Mississippi Valley and elsewhere. The value of the shells secured outside of the United States, principally mother-of-pearl shells, amounts to \$5,000,000 or \$6,000,000 annually. and the pearls secured sell for nearly an equal amount. Pearls are not obtained in the seas in such large quantities as formerly, but their value is greatly increased. The manufacture of mother-of-pearl and sweet-water shell in the form of buttons, buckles, knife-handles, pistol-stocks, etc., gives employment to nearly 10,000 persons in this country and to probably three times that number in Europe and elsewhere.

The yield of whalebone in the United States fisheries is less than 5 per cent as much as it was 50 years ago, but the reduced yield has been largely counterbalanced by the increase in value per pound. The product in the American fisheries now approximates 120,000 pounds each year, worth \$500,000, and about \$150,000 worth is obtained in all other parts of the world. At the present market price the total value of whalebone secured in the United States fisheries since 1850 is not far from \$200,000,000.

Comparatively little tortoise shell is produced in this country, the annual yield approximating \$12,000 in value. The West Indies, South America, Africa, East Indies, Pacific islands, etc., supply probably \$500,000 worth each year, much of which is manufactured in the United States.

Little economic use is made of fish scales, except in the production of artificial pearls and other ornamental objects. Unique and attractive artificial flowers are made from the scales of sheepshead, tarpon, drum-fish, channel bass, etc.

Cuttlebone and coral are not produced in the United States, but large quantities are imported into this country. The yield of ivory in the form of walrus tusks, sperm-whale teeth, etc., is small at present, amounting to less than \$25,000 annually.

The principal industrial use for bones of aquatic animals is for conversion into fertilizer. Several varieties of curious bones are used for ornamentation, but their aggregate value is inconsiderable.

The sponge output of Florida approximates \$500,000 annually, and the value of the product throughout the world is probably not far from \$5,000,000.

The uses of seaweeds are numerous. They furnish thousands of tons of fertilizer, many nutritious foods, and a variety of chemicals, especially iodine and bromine. Other uses are in sizing fabrics, as a mordant in dyeing, in refining beer, in making paper, fishing lines, ropes, for stuffing upholstery, packing porcelain, etc. The Japanese have been especially adept in discovering uses for seaweeds.

Glue-manufacture provides an outlet for the profitable use of much waste in dressing dried codfish. This material was formerly discarded as useless, but now tens of thousands dollars' worth of choicest glue for postage stamps, court-plaster, adhesive paper, labels, envelopes, for mechanical purposes, and for sizing of straw goods and textile fabrics, and likewise office and domestic mucilage are manufactured from fish skins. The product is very much stronger and more durable than glue made from the skins of mammals.

Isinglass made from the sounds or swimming bladders of sturgeon, hake, cod, squeteague, etc., is used for elarifying fermented liquors, the cellular construction forming a sort of net which carries down floating particles. However, the use of this material has been much reduced, owing to the numerous substitutes obtained from domestic animals.

Commercial albumen may be made from the eggs of cod and other species, but it has not yet been extensively manufactured.

The preparation of oils and fertilizers, to which the present report is devoted, is intimately associated, especially in the case of the menhaden industry. The tissues remaining after the extraction of oil from herring and other waste fish, from the blubber of seals, porpoise, and the like, from the livers of cod and related species, the livers of sharks, from the waste parts of fish in dressing, etc., are commonly prepared for fertilizing purposes, and the preparation of the two materials is usually carried on in the same factory and in some instances by the same workmen. For this reason it appears desirable to combine in one paper the account of the preparation of oils and fertilizers from aquatic products. This paper, however, is divided into two parts, one relating to the preparation, characteristics, and uses of fish oils, fats, and waxes, and the other to the utilization of aquatic products as fertilizers.

FISH OILS, FATS, AND WAXES.

GENERAL REVIEW.

Previous to 1600 there was comparatively little demand for oil of any kind. Tallow dips, pine knots, and the like afforded the principal means of illumination. The quantity of machinery in use was small and lubricants were in little demand. The leather industries were undeveloped and the greases required in currying were obtained principally from the fat of the animal furnishing the skin, supplemented later by certain vegetable oils.

The value of whale oils for purposes of illumination was not unknown previous to the seventeenth century, but the fishermen were unequal to the task of capturing the cetaceans, in large numbers. A few that drifted ashore were secured, the use of the oil for illuminating purposes developed; and, as the experience and daring of the fishermen increased, their wanderings extended not only offshore, but to distant seas. After the invention of the Argand burner in 1784, whale oil became the principal illuminating agent, and at the beginning of the nineteenth century it was in general use. Not only were residences lighted with it, but also streets and municipal buildings. A large quantity of sperm oil was used in residences of the wealthy and also in lighthouses, that being the principal illuminant in the coastal lights of the United States, England, Scotland, Ireland, France, and other advanced countries up to 1832. The currying trade had in the meantime increased in importance, and grease for softening was secured in the form of oil from seal, walrus, sea-elephant, cod livers, etc. The increasing use of machinery resulted in an enhanced demand for a lubricant, which was generally furnished in the form of sperm oil. This resulted in very high prices; sperm oil, for instance, ranged from \$1 to \$2 per gallon, although the fishery increased until it was one of the most important organized industries of the world. Other fish oils became important commercial products, including oils from the livers of cod, haddock, sharks, etc., from herring, menhaden, sardine, pilchard, and other species of the *Clupeidæ* family, and a miscellaneous variety of minor importance.

The continued upward tendency in prices, as a result of an increased demand, led to endeavors to find substitutes. Lard oil was successfully introduced as a summer lubricant in the place of sperm oil for ordinary uses. Colza or rape-seed oil likewise entered into competition with it as an illuminant, and the process of refining was improved until it became a fairly satisfactory substitute at about half the price. In 1832 France adopted colza in place of sperm oil as a light-house illuminant, and in 1845 it was adopted in the light-houses and lightships of Great Britain. The difficulty of obtaining rape-seed oil in the United States and the importance of the whaling industry to the national welfare caused the use of sperm oil in this country for ten years longer, when through the researches and experiments of Professor Henry it was found practicable to use lard oil, and in 1862 that became the illuminant in the light-houses of the United States. A few years later both colza and lard oils were superseded by forms of petroleum.

Not only did the products of petroleum take the place of aquaticanimal oils as illuminants, but they seriously interfered with them in the markets as lubricants. Then came the development of rendering and refining a large number of vegetable oils, which are now used for many purposes formerly served by fish oils. Among these vegetable products are olive oil, cotton-seed oil, linseed oil, and, to a less extent, palm oil, cocoanut oil, corn oil, etc. The employment of these substances and a large decrease in the abundance of whales have resulted in a great reduction in the extent of the whale fishery, the fleet decreasing from 735 vessels in 1846 to 38 in 1902. Those marine enterprises more or less associated with the whale fisheries, as the taking of seals, sea-elephants, walrus, etc., have decreased correspondingly.

Fish oils have therefore, to a large extent, given place to land products, and their diminished sale and reduced price have greatly decreased the prosperity of many fisheries. At present the use of fish oils for illumination as compared with that of mineral oils is very small in those countries where the latter are obtainable, their principal use being in miners' lamps. But among many semicivilized people, especially those of subpolar regions, marine-animal oils are more easily obtained than petroleum, so that the native products continue in use. And notwithstanding the large amount of mineral oils now used for lubrication of heavy machinery, there is yet an extensive demand for fish oils for that purpose, experience having shown that by their judicious blending with hydrocarbon oils a greater uniformity of lubrication is secured, and that less quantity is required than by use of mineral oil alone. The outlook for an increased use of fish oils in leather-dressing is said to be not encouraging, owing to a decrease in "hand-stuffing" and the increasing popularity of chrome tannage, in which only a small quantity of oil is required, and that usually a superior quality of neatsfoot. There is a wide field of technical uses wherein certain fish oils can not readily be dispensed with, especially for lubricating delicate machinery, in steel-tempering and screwcutting, as a body for paints to be applied to out-of-door surfaces, in the textile trades where only saponifiable oil can be satisfactorily employed, etc.

In addition to their many technical uses, marine-animal oils are also used for nourishment to a considerable extent. The Eskimos and other primitive people depend very largely on the blubber of seals, walrus, and whales, for food supplies. Among more civilized nations fish oils are not used ordinarily as an article of diet; an exception, however, is the well-known and valuable cod-liver oil, of which twenty or thirty thousand barrels are annually consumed in cases of malnutrition. Certain therapeutic qualities are also attributed to various minor oils, as those from the shark, culachon, manatee, dugong, alligator, terrapin, etc., but the use of these is not general.

The marine-animal oils are divisible into four principal groups, viz: (1) blubber oils; (2) head oils; (3) liver oils, and (4) body oils. The blubber oils are obtained from the layer of fat between the skin and the flesh or muscular tissues of whales, seals, walrus, sea-lion, porpoise, black-fish, etc. Head oils are secured from cavities in the skull and from other head parts of sperm whales, black-fish, porpoise, sword-fish, halibut, etc. Some of these are of superior quality, as those of the black-fish and porpoise, for instance, which sell for \$5 to \$10 per gallon. The head oil of the sperm whale yields the valuable spermaceti. Those of the third group are obtained principally from the livers of cod and to a less extent from haddock, hake, pollock, cusk, ling, sharks, and skates. The bodies, heads, and viscera of these fish are so slightly oleaginous that they are rarely utilized economically for oil purposes. The body oils, or fish oils, " as they are now generally known commercially, are obtained principally from species of the herring family-the menhaden in America, the herring, sardine, and pilchard in Europe, and the iwashi in Japan. In case these fish are used for food in large quantities, the viscera are generally devoted to oil-rendering. Most of the other species of food-fish contain so little oil that it is profitable to use only the intestines or other refuse dressings for this purpose. And in some the yield of oil is so small that not even the waste parts can be profitably utilized in this manner. In addition to the foregoing, there are a number of oils produced in various localities which enter largely into the domestic economy of those procuring them and yet are of little commercial importance, as alligator oil, turtle oil, terrapin oil, etc.

The total annual product of crude oil from marine animals throughout the world is estimated at 18,300,000 gallons, of which 5,500,000 represents the product from the blubber and fat of whales, seals, and the like; 5,300,000 gallons is from the livers of cod, shark, etc., and 7,500,000 gallons from menhaden, herring, sardine, and other species, including waste in dressing fish.

Even a brief survey of the fish-oil industries reveals the fact that they are not by any means so extensive as the natural resources permit. True, the right-whale fishery is prosecuted apparently to an

[&]quot;a The term "fish oil" is used by chemists and other technologists as comprising oils from all aquatic animals. Previous to 1800 it generally referred to whale oils. At the present time its commercial use is generally confined to oils obtained from fish alone. In a restricted sense it refers especially to oil obtained from the principal species of the herring family in the locality in which the term is applied. Thus "fish oil" on the Atlantic coast of the Unite States indicates in a restricted commercial sense the oil of the menhaden; in Norway, the herring; in France, the sardine; in Japan, the iwashi, etc.

extreme limit, and the same is possibly true of the seal fisheries of certain regions. However, there is probably no other oil-yielding fishery of which the same can be said. Sperm whales are more numerous than they were fifty years ago, when the United States employed 300 vessels in their capture, securing 100,000 barrels of oil annually, as compared with the present product of less than 20,000 barrels. Porpoise and other small cetaceans exist in such large numbers that hundreds of thousands if not millions of gallons of oil can be secured from them. Only a very small percentage of the oil-yielding sharks are utilized. Much greater quantities of menhaden might be taken than are secured at present, and comparatively little of the abundant waste fish and dressings or refuse from the markets, canneries, etc., are used in oil-production.

The principal reason for this is that the present economic conditions do not warrant an extension of these industries. The market for fish oils is regulated by that of the mineral and vegetable products which are used as substitutes, and which can be sold at very low prices, making it necessary to exercise very great economy in the production of fish oils. Vessels, factories, etc., already on hand may be used, but in the United States at least it is questionable whether the building of new and costly equipment for oil-production would prove profitable under present market conditions except in specially favorable instances, unless the closest economy be practiced. The vessels composing the present sperm-whaling fleet, for instance, may be kept employed with a fair profit, but with the present prices the fitting out of expensive new vessels can scarcely meet with a large return on capital invested. The present equipment of menhaden steamers and factories was built and paid for during a period of prosperity, when menhaden oil was high in price, and they may be continued in service with profit, but the conditions are not encouraging for a great extension of the industry. If a profitable market could be found for the product, the yield of fish oils throughout the world could probably be increased many times its present extent.

THE WHALE OILS.

BRIEF REVIEW OF THE WHALING INDUSTRIES.

It is scarcely within the province of the present report to enter into a detailed history of the whale fisheries, unquestionably the most picturesque and once the most extensive of all marine industries of the world. In order, however, to present a fair idea of the production and utilization of whale oils, it is desirable to review briefly the history and present conditions of these industries.

Whales are divisible into two groups, (1) toothed whales and (2) bone-bearing or whalebone whales. To the first group belongs the sperm whale or cachalot, which yields sperm oil, spermaceti, ivory, and ambergris. This group also includes the bottle-nose whale, the

pilot whale, the beluga or white whale, and many species which are not popularly known as whales, including the narwhal, grampus, orca or killer, dolphins, porpoises, etc. The bone-bearing whales are divisible into two classes, (a) smooth whales and (b) furrowed whales, or rorquals. The first embraces the right whales of different species and the bowhead or Arctic whale, all of which are prized for their oil and baleen. Of the rorquals, or those whales possessing longitudinal folds of blubber on throat and stomach, may be mentioned the humpback, finback, sulphur-bottom, and California gray whale. As these are ordinarily difficult of capture and are of minor value, the whalebone being rather short for commercial use, they have not been pursued so extensively as have the sperm, right, and bowhead whales. In the United States markets the standard varieties of oils are "sperm oil" and "whale oil," and sometimes "humpback oil." "Whale oil" is a mixture of the product of all whales except the sperm whale, and sometimes includes that of black-fish and walrus.

The use of whale oil appears to be of ancient origin. Doubtless it was first obtained from whales accidentally stranded on the shores, a more frequent occurrence during the early abundance of the cetaceans than at present, when their numbers have been so greatly reduced by excessive fisheries. As the demand for the oil increased beyond the supply available from stranded whales, individuals sighted from the shore were attacked and beached. Owing to the frailty of the boats and equipment, this was a more daring attempt than might be supposed. It is difficult to trace the origin of the fishery, but certainly it was prosecuted a thousand years ago.

Just prior to the Revolutionary war, according to Starbuck and other authorities, there were 183 American vessels in the right-whale fishery of the North Atlantic waters, and 125 were engaged in cruising for sperm whales from Newfoundland to the coast of Brazil. The Revolutionary war and the war of 1812 interfered with the fisheries; but during the period of peace following 1815 they increased greatly in extent until 1846, when the fleet numbered 678 ships and barks, 35 brigs, and 22 schooners, a total of 735 vessels, with an aggregate tonnage of 233,189 tons, and a value of \$21,075,000, exclusive of outfits and supplies. The entire capital invested in the fishery and its associated industries at that time approximated \$40,000,000, and 40,000 persons derived from it their chief support. During the same year the whaling fleet of all Europe numbered but 230 vessels. The crude value of the American catch from 1840 to 1860 averaged about \$8,000,000 annually. The greatest value was in 1854, when 2,315,924 gallons of sperm oil worth \$1.483 per gallon, 10,074,866 gallons of whale oil worth 595 cents per gallon, and 3,445,200 pounds of whalebone worth 39½ cents per pound were secured, the total value being \$10,802,594. In the preceding year, 1853, the total product was 3,246,925 gallons of sperm oil, 8,193,591 gallons of whale oil, and 5,652,300 pounds of whalebone, the whole valued at \$10,766,521.

Sperm oil and whale oil then served nearly all the diversified uses for which oil was required, the chief exception being leather-dressing, for which neatsfoot and cod oils were largely employed. The principal uses were as illuminant, lubricator, in cordage-manufacture, screw-cutting, and steel-tempering. The streets of the principal eities were lighted with the oil, and theaters and public buildings were lighted with gas made from the foots. A stock anecdote at the time referred to foreign sailors climbing up the posts of the New York street lamps to drink the whale oil, thus leaving the city in darkness.

The extent of the fisheries soon began to tell on the abundance of the whales, necessitating much longer and more costly voyages, and consequently higher prices for the products. With the increased price came the active search for substitutes, and colza oil and lard oil were largely employed. The competition, however, had little effect on the market for whale products until the adoption of petroleum as an illuminant, and subsequently as a lubricant. Its dangerous qualities at first greatly checked its use, but as improved methods of refining were introduced it was quite generally adopted and proved most influential in decreasing the profits of the whale fishery.

The restricted market and the reduced price resulted in a gradual decrease of the whale fishery. Various agencies accelerated this decrease, while others retarded it. Among the former may be mentioned the destructive influences of the civil war, including the sinking of 36 vessels in blockading Charleston Harbor, and the burning of 46 vessels, with outfit, supplies, and cargoes by privateers; also the loss of 33 ships in the ice of the Arctic Ocean in 1871, and a similar abandonment of 12 vessels in 1876. Among the agencies tending to retard the decrease in the fishery is the greatly enhanced value of whalebone, which increased from 13 cents per pound in 1833 to \$7 per pound in 1891. Indeed it is the whalebone market alone which sustains the present right-whale fisheries of the world. The table on page 204, showing the annual product of sperm oil and whale oil from 1860 to 1902, inclusive, presents a fair idea of the gradual reduction in extent of the American whale fisheries. Owing to the decreased extent of the fishery, sperm whales are increasing in numbers and are apparently more abundant at present than at any time since the fifties. The bowhead and right whales, however, are doubtless more scarce than at any time since their capture became an object of commercial pursuit.

In 1901, the 20 sperm-whalers cruising in the Atlantic Ocean met with good success, especially those on the Hatteras and Charleston grounds, securing 12,550 barrels of oil, according to the *Whalemen's Shipping List*, an average of 627 barrels to each vessel. The same season in the Arctic and North Pacific, however, was the poorest for many years. The fleet there consisted of 11 steamers and 6 barks. Three steamers were lost, and the total catch was only 43 bowheads and 13 right whales, as compared with 80 bowheads and 14 right whales in 1900. The yield of oil approximated 2,870 barrels, and of whalebone 105,150 pounds. Five barks were employed in spermwhaling off the coast of Japan, taking 4,100 barrels of oil. The market for sperm oil in 1901 opened at 55 cents per gallon, but gradually increased and closed the year at about 68 cents per gallon. The price of whale oil at San Francisco was 32 to 38 cents and in the Eastern markets 38 cents per gallon.

In 1902 the whaling fleet of the United States consisted of 8 steamers, 18 barks and brigs, and 12 schooners, aggregating 8,366 tons. Of these, 11 barks and 10 schooners were sperm-whale fishing in the Atlantic Ocean, 8 steamers in the Arctic, 6 barks in Okhotsk Sea and off the coast of Japan, 2 schooners in Hudson Bay, and 1 brig at Desolation Island.

The total whale-oil product of the world at present approximates 3,000,000 gallons yearly; of which 750,000 gallons are produced by the United States fisheries, 900,000 by those of Norway, and the remainder by Scotland, Russia, Japan, Newfoundland, and other countries.

THE BLUBBER AND ITS YIELD OF OIL IN DIFFERENT WHALES.

The blubber is a layer or blanket of fat lying between the skin and the flesh or muscles and encompassing the bodies of all cetaceans and likewise of most of the other aquatic mammals. It varies in thickness from 1 to 22 inches, according to the species, size, and condition of the animals. The blubber of right whales is thicker, on an average, than that of the cachalot or sperm whale, although an individual of the last-named species has afforded fat 22 inches thick. The blubber of most species is tough and elastic, but that of the humpback is soft and yielding, and the ropes and chains encompassing it tear out easily. The blubber of poor whales is hard, compact, and tenacious; but when the animals are fat it is softer and yields oil readily, even when handled. In color it varies from a vellowish or dirty white to a somewhat unusual pinkish or reddish cast. The whitish blubber is usually found on young whales, more especially sucking calves, and is of a milky appearance. That of old whales has a coarse grain, and yields or gives out the oil freely; hence it is not so difficult to boil as is the fat of young whales, from which it is almost impossible at times to extract the oil, the texture being so fine and close.

In case of the baleen whales the blubber from all parts of the animal is commingled and boiled together. With the sperm whale, however, the process of saving the oil is different. The most valuable oil of this species is found in a large cavity or reservoir known as the "case," situated anterior to the cranium, which yields clear oil and spermaceti, in equal quantities. These products are known as "head matter." Lying beneath the case is a wedge-shaped mass of pinkish

fat, composed of oil, spermaceti, and "white horse," the last being an extremely tough and sinewy blubber-like substance found about the head and neck, as well as upon other parts of the whale. The lower anterior portion of the junk, known as the "nib end," is similar to the body blubber and devoid of spermaceti. Spermaceti is also found on certain parts of the body, especially in the core of the "hump" and about the "ridge," situated along the back toward the "small," but not in so great abundance as in the case. The yield of the head averages about one-third of the total oil-product of the sperm whale. Instances have been reported, however, in which it has been 50 per cent and even as high as 60 per cent of the total.

The following parts in the sperm whale are utilized as an oil-yielding product: The body blubber, case, junk, hump, ridge, lower jaw, head skin, scalp, small flukes, vertebræ, and fin bones. The bones of all whales are porous or spongy in texture, and the cavities are filled with more or less oil. The small bones, such as the fin bones and the vertebræ, as well as the "pans," or broad posterior extremities of the lower jaw-bone, are chopped up with axes and boiled out. The cranium, or, as it is known to whalemen, the "scalp," is generally thrown overboard, but sometimes it is chopped up and boiled. The "head skin," or the great mass of fat covering the scalp, may be rendered if whales are scarce, but when they are plentiful its utilization is not profitable. Some of it is exceedingly tough, and the small quantity of oil it contains is difficult of extraction.

Whales are generally rated by the amount of oil which they yield rather than by the size or length. The yield is expressed in barrels, and an animal may be a "40-barreler" or a "100-barreler." In appearance they are often deceptive, the largest ones not always yielding the greatest amount of oil. Usually the whalemen approximate the product with remarkable accuracy, but sometimes their guesses miss the mark widely. Blubber yields about 75 per cent of its weight in oil, 4 tons of blubber producing about 3 tons of oil, each containing 252 gallons wine-measure. Sperm whales yield from 5 to 145 barrels of oil, averaging about 25 or 30 for the cows and 75 to 90 for the bulls.

The oil-producing parts of the right whales are the body blubber; the tongue; the head gear, comprising the head, scalp, throat, lips, and head skin; and the blubber on the fins. The right whales yield a larger quantity of oil than the cachalot, and the bowhead or Arctic whale yields a larger quantity than the right whale of temperate waters. In 1861 the *General Pike*, of New Bedford, took a right whale on the Kadiak ground which stowed down 274 barrels of oil. The schooner *Lizzie P. Simmons*, New London, killed a bowhead whale on October 28, 1882, in Cumberland Inlet, which yielded 2,550 pounds of whalebone and 6,000 gallons of oil, the value of the former being \$7,687 and of the latter \$3,500, a total of \$11,187 from a single animal. According to whalemen, the right whales now captured are not so large as formerly, but the sperm whales seem to average about the same.

The humpback whales and the finback whales of all oceans are frequently captured by deep-sea whalemen and often by shore whalemen, especially in the Finmarken fishery. Since both of these varieties usually sink when killed, they are rarely hunted except "on soundings." The oil-yielding portions of the humpback are the body blubber; head skin; lips, which are small; tongue; entrail fat, the source of a large percentage of the oil, and the striated folds of fat on the breast and abdomen. The entrail fat resembles very closely in appearance the corresponding fatty substance of the ox; its oil is of the same grade as that of the blubber of this species, which is equal in grade to the oil of right whales.

Not only are the oil and whalebone yielded by finback whales much less in quantity, but they are also inferior in quality to those obtained from the right whales. For this reason, and also on account of their great activity and the difficulty of capturing them by harpooning, they were formerly neglected by whalers; but since the employment of steam vessels with bomb guns and explosive lances an extensive fishery for them has been established on the Norwegian and Newfoundland coasts and minor fisheries on the coasts of Russia and Japan.

The California gray whale is occasionally taken in the lagoons of Japan and on the west coast of the United States. The oil-bearing parts of this species which are utilized are the body blubber, head skin, throat, lips, flukes, and entrail fat. According to Capt. George O. Baker, of New Bedford, during several years following 1866 a brig from New Bedford, Mass., made quite a business of catching California gray whales for the food markets of Japan.

The bottle-nose whale, so called from the peculiar shape of its head, yields on an average about 12 barrels of oil. The principal places where this species is caught are along the edges of the ice fields of northern Europe, between Bear Island and Iceland, the fishery being prosecuted principally by Norwegians hailing from Tönsberg and Sandefjord. Like the sperm whale, the bottle-nose possesses a quantity of oil in the cavity of the head, which yields spermaceti in the process of refinement. The blubber oil of the bottle-nose comes next to sperm oil in quality. It gives no residuum, and is therefore employed for lubricating small machines, spindles in mills, etc.

Besides the above, a number of minor cetaceans are occasionally utilized for their oil; among them the orea or killer whale, the narwhal, the beluga or white whale, the black-fish, and the porpoise. These have a coating of blubber ranging from one-half to 4 inches in thickness, and, although not extensively sought after, many are taken in various parts of the world.

The beluga is plentiful in the Arctic seas and in the North Pacific and comparatively numerous on the Labrador coast and in the St.

Lawrence River, where it forms the object of a small but profitable fishery. The steam-whalers sometimes pursue and capture it in great numbers in the Arctic, but only when the Greenland whale can not be found, for the yield of oil is small and the animal is so swift and active that it is not readily captured. The adult is from 10 to 15 feet in length, and of a creamy white color. The blubber is about 2 inches thick, and each animal yields from 20 to 100 gallons of oil excellent in lubricating qualities.

The orea affords a good variety of oil, but owing to its aggressiveness it is not often attacked by the whalers. It has occasionally been captured on the New England coast, and has also been taken on the west coast of Africa, especially off Walfisch Bay. The blubber is 2 or 3 inches thick, and similar in color and texture to that of the sperm whale.

The narwhal yields a small quantity of oil, which is used considerably by the Eskimos and Greenlanders. It is ordinarily very pale in color, in fact almost colorless. The narwhal is not usually an object of pursuit by our whalemen, as its capture is surrounded with many difficulties, owing to its retreats in the ice floes. The valuable black-fish and porpoise oils are discussed in a separate chapter.

The following tabulated statement of the yield of oil from the several species of cetaceans has been prepared with much care after consultation with the most experienced whalemen of various ports:

| | Yield of oil in bar- rels of 31 ¹ / ₂ gallons. | | | |
|-----------------------|---|-------|---------|--|
| Species. | Varia- tions. | | Average | |
| Right whale. Pacific | 25 t | o 250 | 90 | |
| Right whale, Atlantic | 25 | 150 | 75 | |
| Bowhead | 30 | 250 | 100 | |
| Sperm whale | 5 | 145 | 45 | |
| Humpback, Pacific | 10 | 110 | 42 | |
| Humpback, Atlantic | 10 | 100 | 40 | |
| Finback, Pacific | 10 | 70 | 35 | |
| Finback, Atlantic | 20 | 60 | 38 | |
| California gray whale | 15 | 60 | 30 | |
| Bottle-nose whale | 4 | 25 | 12 | |
| Orca or killer whale | 1 | 6 | 21 | |
| Beluga or white whale | and a | 3 | 11 | |
| Black-fish | 100 | 4 | 12 | |

The methods of cutting-in and removing the blubber have already been described by numerous writers, and especially by James Temple Brown,[«] rendering unnecessary any extended description in this paper.

Suffice it to state that the whale is attached to the side of the vessel, and by cutting in a spiral line and at the same time rolling the cetacean, the blubber is removed in a helical strip 5 or 6 feet wide, and this is boarded in lengths of 12 or 15 feet, called "blanket-pieces." The manner of doing this and of boarding the head gear is germane to nautical engineering rather than to the subject of oil-rendering.

"Fishery Industries of the United States, Vol 2, Sec. 5, p. 278.

REMOVING BLUBBER FROM WHALE BEACHED ON CALIFORNIA COAST.

TRY-WORKS ON MODERN WHALER, LOOKING AFT.

CONVERSION OF THE BLUBBER INTO OIL.

The following notes on the present methods of converting whale blubber into oil are the results of inquiries and investigations made by the writer during the last four years, and especially in October, 1901, when many practical whalemen were interviewed. Especially are we indebted to Capt. George O. Baker, Capt. Charles H. Robbins, Capt. James Avery, and Mr. W. R. Wing, of New Bedford, Mass.

The reduction of oil from the solid mass of blubber, though tedious in detail, is an operation of simple character, requiring merely that the substance shall be exposed to heat. The blanket-pieces, 12 or 15 feet long and 5 or 6 feet wide, are first "leaned," consisting in removing the pieces of muscles which cling to the fat during the process of cutting-in. By means of spades they are cut into smaller sections, called "horse-pieces," about 2 feet long and 6 inches wide. These are passed to the mincers. If the blubber is too thick, say over 12 inches, it is sometimes split before it is minced.

Two methods of mincing the blubber are employed, viz: by hand and by machinery. The former was the first adopted and is generally used at the present time. It is extremely laborious, but most whalemen prefer it, since the pieces are minced more uniformly and consequently the oil boils out more freely. The horse-pieces are laid lengthwise and with the flesh side downward upon a bench called the "mincing-horse," and are scored or cut into slices varying from one-fourth to three-fourths inch thick, called "minced horse-pieces." The knife cuts through the skin, but is stopped within about an inch of the base, so that the slices are held together like the leaves of a book, and in this condition they are pitched into the try-pots.

The try-works are built of brick athwartships between the foremast and the mainmast. The usual dimensions are 8 or 10 feet long, 7 or 8 feet wide, and about 4½ feet high. The first course of bricks, or the base, is laid in openwork, forming channels through which the water may freely circulate. The fireplaces, or "arches," as they are known aboard a whale ship, are strengthened by pieces of iron and are furnished with sliding doors. Two large metallic try-pots are placed within the try-works, with their bottoms resting upon the arches or furnaces. These are shaped like the old-fashioned 3-legged pots so intimately associated with the domestic hearths of our forefathers. They range in capacity from 120 to 200 gallons each.

While boiling the blubber, the fires are kept up day and night. Naturally, the fuel supply is an item of no small consideration to the whalemen. A quantity of cord-wood, each stick sawed into two pieces, and all kinds of refuse wood are included in the vessel's outfit and relied upon for starting the fires. But when fairly under way the highly combustible residue of the fat, known as "scrap," is mainly depended upon. Once in awhile a whale is secured so fat that the scrap is not sufficient to keep the fires going and the "fat lean" and

similar materials are burned, and sometimes even a part of the rich blubber is consumed as fuel in order to save the remainder.

It is well known that the boiling point of oil far exceeds that of water. So intense is the heat at times that the solder upon the implements used about the pots is melted. It is important that all water should be expelled in order that the oil may not become rancid when barreled. It is equally important that every precaution should be taken to prevent water from getting into the pots during the process of boiling, the action of the oil under such circumstances depending upon the quantity of the extraneous fluid which is suddenly brought in contact with it. If the pots are not sheltered heavy rain may cause the oil to foam up, and when the vessel ships a heavy sea or when a very heavy rainsform occurs, the contents of the pots are apt to throw up an immense cloud of steam and scatter the seething oil. Communicating with the fire, the oil is ignited with a flash, and the streams of burning liquid pour out upon the deck, sometimes with disastrous effect. As soon as the contents of the pots show a tendency to boil over, pieces of fresh blubber are pitched in, and if this is not sufficient the fire is immediately banked.

To prevent the vagrant pieces of lean which have accompanied the blubber from clinging and burning to the side and bottom of the pot and thus darkening the oil, the boiling mass is vigorously stirred. This is one of the most important duties in the process of oil-rendering.

Instruments are never used on a whale ship for testing the heat or culinary condition of the oil; the men rely mainly on their experience as to the best time for removing it, judging either by the color of the scrap or by spitting into the boiling mass, this producing a peculiar crepitating noise when the blubber has been sufficiently cooked.

As fast as the pieces of blubber are resolved into oil, the residuary fragments are transferred to a rough box called the "scrap-hopper" or "strainer-cooler." Its size depends upon the dimensions of the try-works, but usually it holds from 1 to 1½ pots of scrap. It consists of two compartments, the upper portion, or hopper, for the scrap and the lower part for the oil, the two separated by a wooden partition containing numerous holes, so that the oil may readily drain from the material.

The best and most economical way of utilizing the scrap has always been an important problem to the whalemen. The body of the sperm whale usually boils out freely, and consequently the scrap is dry, contains little oil, and is valuable only as fuel. The refuse of the right whale, however, retains considerable oil, and the whalemen are averse to burning it until after they have extracted the oil by compression. The scrap from both the sperm and the right whales is regarded as an important fuel supply and is economically saved at each fare during the voyage and used for boiling the blubber of whales taken subsequently.

Although the oil may be thoroughly cooked when the first scrap

is removed, it is not bailed off, the usual plan being to fill the pot with fresh blubber and again boil it down until the pot is full. In this manner the hot oil melts the cold blubber and the latter reduces the temperature of the oil already rendered.

The bones of cetacea contain more or less oil, but they are utilized in oil-rendering only when whales are scarce. On a good voyage the endoskeletons are thrown overboard as fast as the coating of fat is removed, provided they are not required for fuel.

The blubber of the "small" and the lobes of the flukes are cut into horse-pieces and boiled out with the body blubber, being of the same nature. The entrail fat of the humpback whale may be boiled by itself or with the blubber, whichever is more convenient, the oil of the fat and that of the blubber being of the same grade. The fins of the sperm whale are cut up with spades; the fatty covering is boiled with the body blubber, and the bones with the fat-lean. The oleaginous covering of the fins of the right whale is cut into horse-pieces and boiled with the body blubber; the fin bones of this species are rejected. The head skin, or the fatty covering of the crown of both the right and bowhead whales, and, indeed, the "headgear" of both, are cut into horse-pieces and run through the pots with the body blubber.

The tongue of the bowhead as well as of right whales is also reduced to horse-pieces and boiled out. The tongue blubber is close-grained, or of much finer texture than that of the ordinary blubber, and is usually boiled out last. When "green" its oil is extracted with great difficulty, if, indeed, this can be accomplished at all when cooked by itself, unless very finely minced; hence it is sometimes laid aside and run through the pots in easy stages with the body blubber of the next cut. A muscular, fibrous substance known as "plum pudding" permeates the blubber of the tongues of these two species of whales, extending longitudinally through the central part and in greater abundance near the roots. Most of it is utterly worthless and is thrown overboard when detached from the fat of the tongue. At times, however, when the fat predominates, the "plum pudding" is saved and boiled out with the tongue or the refuse of the whale. It is almost impossible to render it when cooked alone.

The "ginger rolls," or platted folds on the throat and breast of the humpback, are cut into horse-pieces and rendered with the body blubber; but the intermediate substance, resembling "white-horse" in some respects, is extremely tough and elastic, and is absolutely worthless as an oil-yielding substance.

In trying out a sperm whale, either the body blubber or the head matter, including the junk and case, may be boiled out first; but they are never cooked together, since it is not policy to mix the oils, the head oil being worth a cent or two per gallon more than the body oil. The manner of preparing the case and junk for the pots being different, they will be described separately.

If the body blubber is tried out first, the head matter is deposited

in junk casks as fast as it is whipped or bailed from the case. The junk is reduced to horse-pieces, placed in similar receptacles, and held in reserve with the head matter until the body blubber has been disposed of. The junk casks are ordinary oil casks with one head removed, and vary in capacity from 100 to 300 gallons each. They are also used to hold the scrap which is saved as fuel. Instead of the casks some of the larger vessels have one or two tanks between decks, which are used as temporary receptacles for the head matter and also for storing the oil.

When ready to boil out the head, the try-pots are well scrubbed, greater care being taken than when boiling the body blubber. They are next about half filled with some of the head matter as soon as it is bailed from the case, the remainder being stowed away as just mentioned. With legs and feet bare, men get into the pots and. standing in this odorous compound, squeeze out the soft pieces of The oil flows freely between their fingers into the pots, while the fat. refuse, called "twitter," is thrown into another receptacle, called the deck-pot, or perhaps into scrap-tubs. Notwithstanding the many improvements that have been made in the oil industries, no process of eliminating this membranous texture from the crude sperm oil has vet been discovered except the one just referred to-that of squeezing by hand. It is necessary to remove these fibers to prevent them from charring and darkening the oil. The case being carefully squeezed, the fires are started and the cooking then commences. The pots are spaded constantly to prevent the small but sometimes numerous particles of twitter, which have not been removed, from burning against the sides and bottoms. Meantime other men are squeezing out the remainder of the head matter deposited in the junk cases, and this is kept in scrap-tubs and poured into the pots as soon as the first installment has been properly cooked and bailed off, this operation continuing until all the head matter has been boiled out.

While the case is boiling, some of the crew cut the junk into horsepieces somewhat larger than the body-blubber horse-pieces, and these sections, after mincing, are pitched into a pot of thoroughly cooked head matter. The hot oil of the case soon dissolves the junk, the two mingling most intimately, being of a kindred nature. Sometimes the case and the junk are boiled separately.

White-horse in considerable quantity ranges through the junk in streaks. It is tougher and whiter in large whales than in small ones. The fatty substance found between these layers, or strata, is soft—about the consistency of butter—and is of a pinkish cast, resembling somewhat in color the meat of a watermelon. The white-horse of large whales, especially of an aged male, is remarkably tough and is detached by means of sharp cutting-spades and thrown overboard. There is little oil in it, and its extreme toughness prevents it from being minced. If attempts are made to boil it out with the junk, it usually soaks up more oil than it yields. But the junk of small whales, more

Report U. S. F. C. 1902,

AQUATIC PRODUCTS IN ARTS AND INDUSTRIES.

particularly the cows, including both the white-horse and the fat, may be cut into horse-pieces, minced, and boiled out together. The process of mincing the pieces of junk and pitching them into the try-pots is identical with that previously described in connection with the body blubber. While some of the men are cutting out the white-horse and preparing the junk for the pots, others are scraping up the oil, which flows out profusely during the operations.

The hump and ridge of the sperm whale are cut into horse-pieces and boiled out with the head and with the fat secured from the jaws.

The term "twitter," which has been previously referred to as applied to the thread-like or membranous substance ranging through the contents of the case, is also applied to the lining of that reservoir. This is from 2 to 3 inches thick, glutinous, and extremely tough. In decapitating the sperm whale, especially in severing near the bunch of the neek, a very sharp spade is required to cut through this tough and elastic formation. Although it is very difficult to manipulate, an economical whaleman never throws this substance away. Since it can not be boiled out with the case, for the reason above given, it is saved and run through the pots with the fat-lean after the case and junk have been cooked.

There are two kinds of "lean," the "clear-lean" and the "fat-lean." The clear-lean, as the term signifies, is composed almost entirely of muscles, and is rejected as utterly worthless to the uses of whalemen. The fat-lean is composed of fat and lean so intermixed that separation by means of knives is impracticable. It is obtained principally about the jaw, as well as from other external parts of the whale. A large portion of it is cut from the blanket pieces during the process of leaning. When whales were abundant, the fat-lean was thrown away, but at present many, if not all, of the whalemen convert it into oil after the oil from the head and body blubber has been boiled out and bailed off. The fires are then drawn, the try-works cooled down, and the fat-lean is pitched in. This is a delicate operation, and if not performed in the proper manner there is danger of cracking the pots. Water is usually placed in the pots first and the fat-lean is pitched in until the pots are about two-thirds full, and then the twitter and lipperings are added. The fires are started, the admixture brought to the boiling point, and the works are again cooled down. When cold the oil floats upon the surface, and the water and cracklings remain at the bottom. If the process has been skillfully conducted, the oil may be almost as light and clear as any obtained from the better and purer parts of the whale. As a rule not more than two pots of this substance are boiled down, for the oil obtained from it is generally more or less sour-a result probably from either mixing it with water when boiling, or because it had become tainted through decomposition, or it may be due perhaps to both causes. This oil is usually barreled separately.

The oil obtained from the fat-lean of one whale is sometimes mixed

197

with that obtained from the blubber of the next capture, this being effected by putting a few gallons of it into the cooling tank every time a pot of the subsequent fare is bailed off. Notwithstanding the importance of keeping the different grades of oil separate, some whalemen adulterate the blubber oil to a greater or less degree by the addition of fat-lean oil, yet they are prudent enough to save several casks of the latter grade to show on their return that the fat-lean has not only been economically saved, but also that its product has not been mixed with oils of higher grades.

The slivers, or small pieces that have been cut and hacked from the blubber while reducing it to horse-pieces and mincing it, are also saved and boiled with the blubber. The "slumgullion" and "lipperings" or "dreenings" of the blubber—consisting of a mixture of the blood which issues from the fat-lean and the salt water and oil which flows from the blubber while the men are handling it as they hoist it aboard ship, stow it away, and prepare it for the try-pots—though discarded in the palmy days of whaling, are now carefully husbanded and amalgamated. Like the sweepings of the floors of mints, this liquid refuse of the eatch is refined in the whaleman's crucible in order that nothing may be lost. After the solid matter has been disposed of, both the deck lipperings and the blubber-room lipperings are usually deposited in barrels or tubs and there scalded with hot oil. The oil thus obtained is raked off and transferred to the cooling tank. In case the lipperings are not clean they are cooked with the fat-lean.

"Slush" is the skimmings from the tops of the pots, and is usually saved by the cook, who is commonly entitled to one-half of it. On arrival home it is sold to manufacturers of soap, and it is even clarified and mixed with lard. At sea the whalemen sometimes eat the slush as a dressing in the form of gravy on sweet potatoes, etc., but it is doubtful if they could be induced to eat it ashore, although it is quite elean and nutritious.

The different varieties of oils are barreled separately. A cask that has contained whale or humpback oil should be thoroughly cleansed before putting sperm oil into it, but a cask that has been used for sperm oil need not be cleansed should it be necessary to use it for whale oil; the small quantity of whale oil that might be left in the cask would perhaps make the sperm oil somewhat heavy, but a little sperm oil would not injure the whale oil. The casks of a ship engaged solely in right-whaling are not marked at all; should the vessel incidentally catch sperm whales, the casks containing oil from this species are marked S O, and the other casks are supposed to contain whale oil. Casks containing right-whale oil taken by a sperm-whaler are marked W or W O. The head oil of the sperm whale, unless the quantity be very small, is always kept in separate packages, which are marked II; those containing the body oil of this species are marked S O or Sp O. The packages of fat-lean oil bear the initials F L O, and black-fish oil B F O. Except when large catches are made, blackfish oil may be kept in meat barrels. The lettering is done in white paint, on the heads of the casks. When the oil is shipped home by another vessel the name of the ship is also branded on the cask, the impression being made with an implement called the "ship's marking iron," and the casks are numbered consecutively.

REFINING SPERM OIL AND WHALE OIL.

The rendering and care of the oil on shipboard having been described, there remains to be discussed its further treatment for commercial purposes, especially extraction of the foots and bleaching. The headquarters of the refiners of whale oils in the United States are at New Bedford, Mass., and San Francisco, Cal. Twenty years ago New Bedford monopolized the business, but large refineries have been erected at San Francisco, and at present about 20 per cent of the sperm oil and 60 per cent of the whale oil are refined at that port. The subjoined description is prepared almost wholly from information furnished by the principal refiners of New Bedford in 1901. The writer wishes especially to acknowledge, in this connection, the courtesies of Messrs. William A. Robinson & Co., and of Messrs. Frank L. Young & Kimball.

As received at the refineries, the casks of oil have been inspected and gaged by customs officers. They may have been kept in storage for months, and in some cases years, before reaching the refiner. Formerly, on the wharves at New Bedford might be seen thousands of casks filled with oil awaiting sale, being preserved from great leakage in the meantime by a covering of seaweeds; but in recent years the quantity has been much reduced, and on the occasion of the writer's last visit to New Bedford (October, 1901) not a single barrel of oil was on the wharves.

The oil is of two principal kinds, viz, sperm oil and whale oil, the former being obtained from sperm whales and the latter from all other varieties of whales and also from walrus, black-fish, sea-elephant, etc. It ranges in color from clear amber to very dark brown, depending on the variety of animal, the condition of the blubber, and the success of the rendering. The quality, is determined by appearance, odor, and flavor. There is some difference in the value of crude oil of the same species of whale from Northern and from Southern seas, the former selling for a few cents more per gallon. Crude sperm oil was formerly worth about double the value of whale oil, but in recent years the difference has been much less. Little use is made of unrefined sperm oil, but considerable of the product of whale oil is sold in a crude state to steel-workers, miners, and cordage-manufacturers.

The products from refining sperm oil are the "winter sperm," which is the first running from the crude oil after it has been granulated by refrigeration; the "spring sperm"; the "taut-pressed," and spermaceti. The refined sperm oils are not generally sold in their natural color, however, but are usually bleached by a process which leaves

"sperm-oil soap" as a product. The products of whale oil, including that of walrus, black-fish, sea-clephant, etc., are the winter, spring, and summer pressings, a tallow-like substance known as whale foots, and "oil soap."

Sperm oil.—The two varieties of oil obtained from sperm whales, viz, body oil and head matter, differ greatly in appearance. The former is of a light straw color, while the latter when first taken from the head of the whale is as clear and limpid as water, but after a short time thickens and hardens into a white mass. Each animal is supposed to yield about two-thirds body oil and one-third head matter. These are kept separate on shipboard, but when received at the refineries they are generally mixed in natural proportions and together submitted to the processes for separating the oil and spermaceti.

In the process of refining, the crude oil is drawn from the casks and heated for the purpose of driving off all the water. This is conveniently done by running it into large iron tanks of several hundred, or even thousand, gallons capacity, where it is subjected to heat by means of coils of steam-pipes running around the inside of the tanks. When heated in excess of 212° F. all moisture is soon expelled, and the oil resists water; that is, water will refuse to mix with it and will "snap" when dropped into the oil. By continuing the heating from six to ten hours the crude oil is converted into a clear liquid state, all particles of fat and blubber boiling out and the impurities settling at the bottom of the tank. The steam is then shut off and, after the oil has partly cooled, it is drawn off from the top of the tank into barrels or casks with capacity of about 50 gallons each. The sediment which precipitates at the bottom is drawn off and made into soap.

In the barrels the oil is chilled. In cold weather, from December 1 to March 31, this is done by exposing the barrels and their contents to the weather; but during the balance of the year it is necessary to place them in large covered pits, where the oil is frozen by using ice and salt packed among the barrels. To avoid the expense of artificial refrigeration, it is preferable to do the refining during the winter season.

After remaining in the pit from ten to fourteen days, at a temperature of about 32° F., the oil is thoroughly chilled, shrinks, and separates or granulates into little balls or grains. It is then removed from the refrigerator, shoveled from the barrels into canvas or hempen bags holding from 2 to 4 gallons each, and placed in a press, where it is subjected to a pressure of from one to two thousand pounds to the square inch. There is thus pressed out a clear, cold oil known to the refiners as "winter sperm oil," which will stand bright or will not congeal at a low temperature fixed as a standard. Formerly the standard was 32° F., but at present the usual commercial test is 38° F. Oil of 23° F. test has been prepared, but there was no demand for it. Since the lower the temperature at which the congealed oil is pressed the less the quantity yielded, it is not desirable to use any lower temper-

GRINDING AND PRESSING CRUDE SPERMACETI FOR REMOVAL OF TAUT-PRESSED OIL.

INTERIOR VIEW OF OIL REFINERY. FILLING BOTTLES WITH SPERM OIL.

ature than required. When producing oil of 38° F. test, the amount of "winter sperm oil" yielded is about 75 per cent of the original quantity. In former times when a 32° F. test was used, the "winter sperm oil" was about 67 per cent of the original bulk. This may be sold either in its natural state or bleached. It is used principally as a lubricant, and, to a less extent, as an illuminant in mines.

After the "winter sperm oil" has been pressed from the bags there remains in them a solid of a brownish color, which is again submitted to pressure at a warmer temperature, say 50° to 60° F., and there is produced an oil known as "spring sperm oil," which congeals at the test of 50° to 60° F. above noted. The quantity of "spring sperm oil" is about 9 per cent of the original quantity of crude oil.

The solid now remaining in the bags is emptied into receptacles and, after remaining for several days at a summer temperature, is dumped out in the form of solid cheese-like cakes. These are stored where the temperature is kept at about 80° F. and in the course of a week or so are shaved up by revolving knives and again bagged and subjected to a pressure of about 100,000 pounds to the square inch. This yields a third grade of oil called "taut-pressed oil," which will chill at a temperature of 90° to 95° F. The quantity of oil of this grade is about 5 per cent of the original bulk, making a total of 89 per cent of refined oil obtained. The residue in the bags after the extraction of "taut-pressed oil" is crude spermaceti of a brown color, which will melt at a temperature of 110° to 115° F. The methods of refining spermaceti are set forth on page 245.

As refined at the present time, sperm oil, including both body oil and head matter, yields about 11 per cent of crude spermaceti and 89 per cent of refined oils, in the following proportions: 75 per cent of "winter sperm," 9 per cent "spring sperm," and 5 per cent "tautpressed oil." A barrel of crude sperm oil of 314 gallons, weighing 231 pounds, yields 25 pounds of refined spermaceti, 23.6 gallons of "winter sperm," 2.8 gallons of "spring sperm," and 1.5 gallons of "tautpressed oil." The prices of these (January, 1902) are: Spermaceti, 23 to 24 cents per pound; winter sperm, 75 to 77 cents per gallon; spring sperm, 60 to 61 cents; taut-pressed, 50 to 53 cents, and sperm soap 3 cents per pound; a total of about \$24.50 resulting from one barrel of crude oil.

Sperm oil is one of the most characteristic and valuable oils in commerce. It is very generally conceded to be the best lubricator in existence for light, rapid machinery, such as the spindles of cotton and woolen mills, its viscousness, tenacity, and high flash-point causing it to work with great uniformity and with a small amount of friction. But there are many cheap substitutes—made from petroleum principally—which, though not so good, answer the purpose nearly as well; consequently the demand for sperm oil is far less than formerly, and even much of that sold as sperm contains a large admixture of hydrocarbon and other oils.

Whale oil.-The color of whale oil depends on the "age" of the blubber, or the time that elapses between the death of the whale and the trying-out of the oil. Usually it is brown, much darker than sperm oil, with a slightly disagreeable odor. In a crude state it is used to some extent by screw-cutters, steel-temperers, cordage-manufacturers, and as an illuminant for miners' lamps, but more than half is refined in a manner similar to the treatment of sperm oil. The first boiling and freezing processes are the same as with sperm oil. When removed from the refrigerator the congealed mass is usually dumped on woolen strainers, 2 feet wide and from 10 to 20 feet in length, stretched across frames. The process of straining is employed to reduce the bulk, since much oil will pass through the woolen cloth and leave a less quantity to be pressed. The thick part remaining on the strainers is placed in bags, as in case of sperm oil, and subjected to great pressure. The first oil from the press congeals at 36° to 40° F. and is called "winter whale oil." The foots or stearin that remains in the bags, averaging one-tenth of the original bulk, and about the consistency of leaf lard, is usually white and clean. This may be reheated and refrigerated, and upon a second pressing yields "spring whale oil" of a higher degree test; but this is not frequently done.

The oil with the foots removed may be sold in its natural color or it may be bleached. One-eighth of the whale oil and probably half of the sperm oil is bleached by the refiners. In this process it is first placed in the refining tanks and heated. When partially cooled the water and sediment are drawn off from the bottom of the tank, and while the oil is agitated or stirred some soda ash or caustic soda is added. This so acts on the oil as to cut the gum, and the thick part gettles to the bottom, leaving the oil clearer and of a lighter color. It is also accomplished by exposing the oil under a glass roof to the sunlight for a few hours, or even days, in large shallow vats or pans from 3 to 12 inches deep, each with capacity for several hundred gallons.

The refuse in the bottom of the tanks is drawn off and boiled down into oil soap, which is worth about 3 cents per pound. The first bleaching will give about 2 per cent in hard soap, the second and third each give about the same. If the oil is clear and sweet the first bleaching is sufficient. Much of the oil soap is shipped to California, Florida, and other fruit-growing sections, where it is employed as a wash for trees to protect them from the ravages of insects. It is also used to some extent in fur-dressing.

In the usual pressings, the oil of the right whale taken in high northern latitudes gives about 8 per cent of foots or stearin; if taken in the vicinity of the equator, or south of it, about 15 per cent of stearin is yielded. Humpback and finback oils yield about 12 per cent of foots; sea-elephant yields 5 or 6 per cent; menhaden from 5 to 10 per cent; and seal oil yields only 3 or 4 per cent in the customary pressings. Of course this varies according to the temperature at which the oil is pressed. Tallow regulates the price, in a measure, as the stearin is substituted to quite an extent for that article. The market price approximates 5 cents per pound. It may be refined in a manner similar to spermaceti, though it is generally sold in the crude shape, packed in barrels. The chemical constituents are mainly glycerides of stearic and palmitic acids, mixed with oil. It is used principally as a sizing for yarns, smaller quantities being used in Europe for smearing sheep after shearing. Other uses are in making soaps and in filling or stuffing leather.

The various whale oils are hard and strong, and range in specific gravity from 0.900 to 0.927 at 59° F. Oil of the right whale has specific gravity of 0.925 to 0.927 at 59° F. Oil from the humpback and likewise from the sulphur-bottom whale is somewhat lighter in weight, the specific gravity varying between 0.915 and 0.920 at 59° F. According to Brannt, the composition of right whale oil is earbon 76.85 per cent, hydrogen 11.80 per cent, and oxygen 11.35 per cent; while that of humpback and sulphur-bottom whales is carbon 77.05 per cent, hydrogen 12.05 per cent, and oxygen 10.90 per cent. Refined whale oil is extensively used in machine shops to reduce friction, particularly in cutting bolts and screws. It is also used as stuffing in leather-dressing, especially in the manufacture of chamois leather.

The following summary, compiled from the trade journals, shows the range of prices per gallon for crude sperm oil and for whale oil during a series of years ending in 1901:

| Year. | | Sperm oil, per Whale oil gallon. gallon | | | | | Sperm oil, per gallon. | | Whale oil, per gallon. | |
|----------------|-------------------|--|--------------|------------------|--------------|--|---------------------------|-----------------|------------------------|--------------|
| 1868 | \$1.75 to 1.59 | | . 84 | o \$1.13 1.13 | 1886 1887 | | . 57 | o \$0.85 .65 | \$0.36 t .35 | . 30 |

Statement of the maximum and minimum prices per gallon of sperm and of whale oil each year from 1868 to 1902, inclusive.

In the early years of the whale fishery nearly all the sperm oil produced in the United States fisheries was exported in a crude condition, and during the period of greatest prosperity in the fishery about onehalf was exported, but at present the exports in a crude state are very small. For the first time in a hundred years none whatever was exported in 1901. Most of it is refined at New Bedford, and some of the refined oil and a large percentage of the spermaceti are exported. Of the whale oil the greater part is consumed in this country.

The annual product of sperm and whale oils, quantities exported, and quantities consumed in this country, are shown in the following:

Table showing, in barrels of 314 gallons each, the production of sperm and whale oils by the whaling fleet of the United States, the export to foreign countries, and the home consumption from 1860 to 1901.

[Compiled from the Whaleman's Shipping List.]

a On hand Jan. 1, 1903, 3,600 barrels sperm oil. b There was no whale oil on hand Jan. 1, 1903.

PORPOISE AND BLACK-FISH OILS.

Among the minor oils of technical importance are those of porpoise and black-fish, which are nearly equal in texture and are used for similar purposes. These oils are in two grades of widely different characteristics, viz, blubber oil and head or jaw oil; the former is worth about the same as right-whale oil, or 35 cents per gallon, while the latter sells as high as \$10 per gallon. They are generally known as "porpoise oil" and "porpoise-jaw oil," respectively, although the black-fish yields many times as much oil of each grade as the porpoise.

Porpoise have at times been taken in considerable quantities in shore (isheries established primarily for securing the hides for tanning purposes. 6,450 porpoise secured on the North Carolina coast in 1887 yielded 10,460 gallons of body oil; 2,283 porpoise in 1889 yielded 3,897 gallons, and 1,747 in 1890 furnished 2,746 gallons.

This oil is pale yellow to brown in color, and has a slight fishy odor, which disappears on exposure to air. The specific gravity, according to Brannt, is $0.918 \text{ at } 59^{\circ} \text{ F.}$, and it congeals at about 3° F. When fresh it is indifferent to litnus paper, but absorbs acid properties from the air. It is used for tanning purposes and in compounding with mineral lubricating oils.

The sperm-whalers of the Atlantic occasionally harpoon Hatteras porpoise from the bow of the vessel and lift them aboard for food purposes. In many cases the blubber of these is removed and tried-out for oil. This blubber is of a yellowish white or pearl color, varies in thickness from $\frac{1}{2}$ to $\frac{1}{2}$ inches, and is of about the same texture as that of the beluga or white whale. It is cut in longitudinal strips 4 or 5 inches wide, minced, and placed in the try-pots with other blubber. The yield of oil is usually less than 2 gallons to each animal, consequently the whalers do not often render it.

From the jaw-pans of porpoise taken more particularly for food, the whalers obtain the highly renowned "porpoise-jaw oil," which is used for fine lubricating purposes. The lower jaw is removed from the head, the pans extracted therefrom with a knife, minced, and placed in a small tin, such as a meat-can, and placed on the stove to simmer or boil gently. The quantity of oil obtained from each jaw is very small, probably about one-half pint, and the total quantity secured by the whaling fleet of New Bedford probably does not exceed 5 or 6 gallons annually, the market price of which is upward of \$6 or \$8 per gallon.

Some years ago the Passamaquoddy Indians on the Maine coast captured numbers of porpoise. Indeed, at one time that fishery furnished their principal means of support. As the animals were taken mostly during the winter and inshore, where food is abundant, they were very fat. The largest individuals measure about 7 feet in length and 5 feet in girth, weighing 300 pounds or more. The blubber of a large porpoise is from 1 to 2 inches thick and weighs 75 pounds and upward, vielding 5 or 6 gallons of oil, but the average for all taken was only 2 or 3 gallons. In the primitive method employed by the Indians, the blubber is stripped off and cut into small pieces, which are placed in a large pot. Inside a semicircle of large stones a fire is made, and when the stones are hot the fire is scattered and the pot containing the fat suspended over the stones and sufficient fire kept up to insure the melting of the blubber. The oil rising to the surface is skimmed off and placed in suitable receptacles. This oil, when pure, formerly sold for 60 to 80 cents per gallon, but was frequently adulterated with seal oil and sold at less price. It gives an excellent light, and also is good for lubricating machinery, as it is free from sticky characteristics and has quite a low weather-test. The superior oil in the jaw-pans is

also extracted by hanging the jaws in the warm sunlight and permitting the oil to drip into cans placed underneath to receive it. About half a pint of this oil may be secured from each porpoise; it is sold at a very high price for lubricating watches, clocks, and the like. Very few of the Passamaquoddy Indians are now left, and these few have almost entirely abandoned "porpusin" for other occupations.

The "black-fish" (*Globiocephalus melas*) occurs in many parts of the Atlantic Ocean. Individuals vary in length from 8 to 22 feet. They are captured by the sperm-whalers, and also at irregular intervals they are secured when stranded on the shore, especially in Cape Cod Bay, where they have gone in pursuit of food, the fishermen getting to the seaward of them and driving them ashore. They are likewise secured on the rocky coast of Secoland and other parts of northern Europe.

According to Capt. James Avery, of New Bedford, the sperm-whalers take them at all seasons of the year and throughout the Atlantic, but probably in greatest abundance on the west coast of Africa in 20° W. longitude, and 6° to 10° N. latitude. The number caught annually has greatly decreased in the last fifteen or twenty years. In 1881 the *Eleanor B. Convell* caught 196, probably the greatest number taken in any one year by a single vessel. During the last three or four years the entire whaling fleet probably has not captured more than 20 or 25 annually, yielding about 800 gallons of body oil and 50 gallons of head oil, the former worth \$280 and the latter \$350 at fisherman's prices.

The black-fish are captured in much the same manner as very small sperm whales, and for cutting-in they are hove up on deck by means of lifting tackle. The blubber is nearly white, from 1 to 5 inches thick, and is removed from the carcass in longitudinal strips 8 or 10 inches wide. These strips are cut in horse-pieces and minced in the same manner as already described for whale blubber, the blood being washed off the fat by dashing buckets of water over it. The minced blubber is then placed in the try-pots and cooked, and subsequently treated precisely as that of the right whale. The product of oil ranges from 5 to 120 gallons. This is sometimes mixed with whale oil, although it has a greater value, selling usually for several cents per gallon more than that of the right whale.

The head oil of the black-fish is taken from the melon or junk and the jaw-pans. The melon is a fatty mass on the top of the head, reaching from the spout hole to the end of the nose, and weighs about 25 pounds. This is washed free from blood, minced, and placed in the try-pot. The lower jaw is cut off, the jaw-pans cut out with a knife, minced, washed, and placed with the cleaned jaws and the melon in the try-pot. Some whalers cook the melon and the jaw materials separately, but the above is the usual method.

It is customary to cook the head matter of black-fish in fresh water. About 15 gallons of fresh water is placed in the pot, the fat is then added, and the whole brought to a gentle boil by means of a slight fire. At this point a little overheating will effect great injury. When the cooking is completed the pot is allowed to cool and the following morning the oil is skimmed off. The product of head oil from individual black-fish ranges from three-fourths of a gallon to 3 gallons, averaging probably about 2 gallons. At ordinary temperatures the blubber oil and the head oil of black-fish are much alike in their appearance, thus furnishing great temptation to the fishermen to mix a little of the cheap product with that of greater value, resulting in much vexation and loss to the refiner, as it is only in the process of refinement that the adulteration is revealed.

In addition to the black-fish secured by the sperm-whalers, large numbers have been captured on the shores of Cape Cod, where they are attracted by squid on which they feed. The animals are surrounded by boats and driven like cattle to the beaches, and are there stranded in endeavoring to escape. They are lanced to death and when the tide falls the blubber and the oil-producing head matter are stripped off and conveyed to try-works on the shore, where the oil is extracted in much the same manner as already described for the vessel fishery.

The greatest eatch of black-fish on Cape Cod was made in 1884. On November 17 of that year 1,500 were killed at Blackfish Creek, South Wellfleet, where they had been driven ashore. About a month later 500 more were slain in a great round-up in the bay. Since that time very few have been secured in the bay, nor have they been seen at sea in any such numbers as previous to the slaughter above noted.

The oil from the blubber of porpoise and of black-fish is refined in precisely the same manner as whale oil, but the process of treatment applied to the head oils is far more complicated. These are very limpid, of an unusually low weather-test, and have little corrosive effect on metallic surfaces, making them when refined superior for lubricating such delicate mechanisms as watches, chronometers, typewriters, etc. Practically all of these oils secured in the American fisheries are refined at New Bedford and Provincetown, Mass., there being two refiners at the former place and one at the latter. We are indebted principally to Mr. William F. Nye and to Mr. Joseph K. Nye, of New Bedford, for the subjoined notes relative to the methods of refining.

In the preparation of watch and chronometer oils much depends upon the freshness of the fat at the time the oil is rendered and the freedom of the material from adulterants. Fresh substance produces much better oil than that which has partly decomposed, the product being sweeter and less rancid. No choice seems to exist between the porpoise-jaw oil and the black-fish-head oil, both producing refined articles of equal merit; but that of the black-fish seems to be the favorite by a slight margin among the refiners, owing to its having more body, and possibly also to its greater abundance. A peculiarity of these oils is that they improve with age, differing in

this particular from blubber oils. This is accounted for by the alternate gathering and emission of moisture upon exposure to changes of temperature, and by this and other treatment they become clear and brilliant, in consequence of which they are seldom used within less than a year or two after they are obtained.

On receipt of the oil at the factory the first step in the process of refining is to gently heat it to complete the process of cooking begun by the fishermen. The oil is then placed in tanks or casks to await the process of grading, and often two years may elapse ere the trained and skillful eye of the refiner can determine to what class it belongs. It is almost impossible to describe the extremely delicate variations in color, texture, odor, and flavor which enter into this grading. The claim is made that there are not half a dozen men in the world who have had the training and experience necessary to separate these delicate oils into their proper classes, and yet a very large part of the reliability of watch and chronometer lubricants lies in the gradation under the almost instinctive skill of the refiner.

According to Mr. Joseph K. Nye:

After two years or more of rest, the oil has got to a condition where its surplus oxygens have united with whatever animal or loose organic matter may have been floating in microscopic particles within it, and they are easily removed by the ordinary strainers of an oil factory. But something is still left in the oil which is very sensible to the high or low range of temperature, and to remove this requires its subjection, while spread out in thin layers, to a temperature far below zero. No further change in its construction can be made except at this very low temperature, nor must it be cooled too rapidly. When properly done the process is one most interesting to watch. All through its liquid amber little flecks of translucent material appear, joining and rejoining like frost on a window pane into most beautiful forms, resembling a miniature forest whose foliage is white. By means of a certain fine and close-grained fabric these particles at this juncture are filtered out; and strange to say, this residuum, once a portion of a brilliant, almost colorless fluid, never even at normal temperature becomes anything but a slimy mass, resembling por lard.

In order to get this low temperature, one of the New Bedford refiners has established a chilling plant at St. Albans, Vt., where longcontinued cold can be depended upon.

To be thoroughly satisfactory the refined oil must be of uniform quality, entirely devoid of acidulous properties, absolutely gumless, withstand the rigors of the coldest climate without congealing, and maintain its body or stability in a high temperature. This is the most delicate and highly refined lubricant known, and some has been produced for which a temperature of -50° F. has been claimed. While all watch-oil users do not prefer colorless fluid, the average customer demands an oil almost if not absolutely colorless and of crystal clearness. Much of the product is sold for repairers' use in wooden boxes containing 1 dozen half-ounce bottles, each bottle inclosed in a small pasteboard box. The remainder, in tin cans having capacity for 1 pint, 1 quart, or of larger capacity, goes to the manufacturers of watches, clocks, chronometers, typewriters, etc.

209

OILS FROM SEALS, WALRUS, ETC.

The blubber or fat lying between the skin and the muscular tissues of the various members of the *Pinnipedia* yields oil of much importance for technical purposes. The principal varieties on the market are from the common seals or hair-seals of the North Atlantic, the walrus, the sea-elephant, and the sea-lions. Each of these will be discussed separately.

SEAL OILS.

Seals are found in various northern waters and especially off the coast of Labrador and Newfoundland, in the waters of Greenland, the Arctic Ocean north of Europe, in Caspian Sea, along the Nova Scotian and New England coasts, in the Northern Pacific, and to a much less extent in the Antarctic seas. The principal fisheries are in the Arctic and North Atlantic oceans, especially off the coasts of Newfoundland, Greenland, and Northern Europe. The Caspian Sea also affords an important seal fishery.

The blubber of seals ranges in thickness from 1 to 3 inches, according to the species, age, and condition of the animals. It is removed from the pelts usually as soon as the latter are landed. If the weather is warm, considerable oil of prime quality flows from the blubber during the process of separating it from the pelt, and provision is made for this free oil to flow into suitable receptacles.

The oil may be at once extracted, or the blubber may be stored for a more convenient season, especially if the weather be cold, as it is much easier to extract the oil during warm weather. If the blubber is stored, it should be in well-ventilated apartments, so arranged that the oil forced out by compression and warmth may run into suitable reservoirs. In the best-arranged storage rooms the reservoirs are oak-wood casks, lined with lead in some instances, with capacity for a thousand or more gallons. These are placed at intervals in the floor, which is so inclined as to cause the oil to flow into the receptacle. The oil which flows under these circumstances is usually clear, sweet, and of prime quality.

There are several methods of extracting the bulk of the oil from the blubber, the one adopted depending to some extent on the proposed use of the product and also on the amount of capital available for equipment and the quantity of blubber to be handled. The methods may be divided into three principal classes, viz, (1) by maceration exposed to solar heat, (2) by cooking in open kettles, and (3) by the application of steam.

The simplest method of extracting the oil is by exposing the mineed blubber in a mass to the weather. The blubber is heaped up in large tanks and—when the temperature is suitable—elear, pale oil flows from the mass. As putrefaction advances and the cellular texture is destroyed, the mass yields oil of a reddish yellow and then a dark brown color, with somewhat disagreeable odor and flavor, owing to the

F. C. 1902-14

decomposition products evolved. When the oil ceases to flow, usually at the end of two or three months, the mass of fat is boiléd in water with the fleshy or fat-lean portions. During this boiling the oil rises to the surface and is skimmed off. The residue is evaporated by pressure and drying, and is used for fertilizer. This was formerly the usual method employed in rendering seal oil in Newfoundland, but during the last twenty-five or thirty years the steam process has been generally adopted.

In treating a small quantity of blubber for extraction of the oil it is usually more convenient to mince it finely and cook it in a kettle over a fire. The oil rises to the surface and is skimmed off and placed in casks or other suitable receptacles. This is the method commonly employed by the shore hunters whose catch is small.

At the large sealing ports, as St. Johns, Tönsberg, Dundce, Astrakhan, etc., the oil is usually rendered by means of steam. The minced blubber is exposed to the action of steam in large inclosed tanks. The oil flowing therefrom passes through pipes into large reservoirs, of which there are usually three or more, the overflow from the first passing into the second, and the overflow from the second into the third. This furnishes the first quality of steam-refined oil. By pressing the steamed blubber, a second quality of dark-brown oil is obtained.

The steam process of rendering has the advantage of rapidity in operation, also the oil is free from disagreeable odor and is of superior burning qualities. However, for use in mines the sun-extracted oil is preferred, especially that of young seals, owing to its greater freedom from smoke, the odor being of little consequence to miners. According to Mr. Carrol,^a oil from old seals is more smoky than that from young ones; it is also of greater specific gravity, and when the blubber of both are rendered together, the young seal oil comes out first.

Although the catch of seals in the Newfoundland fishery in 1901 was almost as large as in 1900, being 345,380 in 1901, as compared with 353,276 in 1900, the yield of oil was about 120,000 gallons less, representing a difference in value of about \$50,000. This was principally because the average weight of the seals was small, owing to the fact that in 1901 the seals whelped some days later than in 1900, and furthermore, they were taken two or three days earlier than usual, the absence of pack ice enabling the vessels to reach them promptly after leaving harbor. In 1900 the average weight of the seal pelts was about 46 pounds, whereas in 1901 it was but 38 pounds. The young seals gain daily two or three pounds in weight of blubber, and if the vessels had been three or four days later in reaching the herds, the yield of oil in the Newfoundland fishery in 1901 would probably have been approximately the same as in 1900.

The decadence of the scal-oil industry, especially in the waters north of Europe, has been gradual but certain, owing to the introduc-

a The seal and herring fisherics of Newfoundland, by Michael Carrol, Montreal, 1873, p. 30.

tion and adoption of cheaper substitutes for the relatively high-priced seal oil. Every year shows a decrease in the number of vessels employed in the fishery, and when a vessel is lost or sold it is rarely replaced. Comparatively little seal oil is imported into this country, the quantity in some years amounting to less than 1,000 barrels. The price in bond approximates 45 cents per gallon. The Newfoundland oils are marketed principally in St. Johns, Glasgow, London, and Leith; those from the waters north of Europe, at Dundee, Copenhagen, Hamburg, and Archangel, and that from the Caspian seal fisheries at Astrakhan.

Seal oils vary in specific gravity from 0.915 to 0.930 at 59° F. According to Braunt, they are composed principally of glycerides of physetoleic acid, of palmitic, stearic, and a small quantity of oleic acid and traces of butyric acid, valerianic acid, etc. They show a slight acid reaction when fresh, the acidity increasing with age. Instead of the albuminous substances present in vegetable oils, the seal oils contain a small quantity of glue which can be precipitated with tannin and metallic salts. They are very slightly soluble in alcohol, and require almost an equal volume for solution in ether. Mixtures of equal volumes of nitric and sulphuric acids produce a reddish color, quickly changing to brown. The adulteration of seal oils is detected principally by the incomplete saponification if resin oil be the adulterant, and by the degree of solubility in alcohol if other blubber oils are employed.

In addition to the pure oils there are several well-known compound seal oils on the markets, the best known being the "three crowns." Greenland "three crowns" is a mixture of several varieties of blubber oil, chiefly seal oil, or rather seal-oil foots, and small quantities of whale and walrus, combined with oil from shark livers, the fluidity and low specific gravity of the shark oil imparting the special qualities to this compound. Swedish "three crowns" oil is a compound of various seal oils with herring oil.

The principal use for seal oil is for burning in miners' lamps, and it is also employed in currying and to a very small extent for miscellaneous purposes, especially fiber-dressing. About 2,500 barrels are used annually as an illuminant in the light-houses in the British North American provinces. Owing to its sluggish nature it is usually improved by the addition of mineral colza. An excellent miners' lamp oil is said to be composed of seal oil, 40 per cent; whale oil, 25 per cent; lardine (0.980), 10 per cent, and mineral colza, 25 per cent.

SEA-ELEPHANT OIL.

The sea-elephant or elephant-seal has furnished a large quantity of oil to the American markets during the last eighty years. The whalers operating in the extreme South Atlantic, and also the fur-sealers sailing to Falkland, South Georgia, and the coast of Patagonia, secured odd lots previous to 1803, but the first vessel specially fitted out for securing this article appears to have been the ship *Alliance*, which sailed from New Bedford in 1803 for Patagonia, and returned home in 1804 with a full eargo of oil. This was the pioneer of a large number of vessels sailing to the Patagonian coast for sea-elephant oil. That coast seems to have been abandoned about 1820 for the South Shetland Islands, which for seventeen years furnished many cargoes to the fur-scalers sailing from Stonington. Since 1837 Desolation or Kerguelen Island has furnished the great bulk of the sea-elephant oil. Heard Island has furnished many cargoes since 1857, but on account of the exposed situation of that island vessels do not usually go there when a cargo is obtainable elsewhere. South Georgia, South Shetlands, and the Patagonian coast also have many sea-elephants and are occasionally visited by the hunters, but the great bulk of the catch has been obtained at Desolation Island.

Although the taking of sea-elephant oil originated with the Nantucket whalers, it has been peculiarly a New London industry since 1820, the neighboring ports of Stonington and Mystic furnishing a number of vessels during certain seasons. From 1820 until the present time 94 per cent of all the voyages have been made by vessels from these three ports, and 80 per cent have been made by the New London vessels. The fleet was largest in 1858 and 1859, 18 vessels, with an aggregate tonnage of 4,527 tons, being employed in 1858, and 20 vessels, with 4,461 tons measurement, in 1859.

The last vessel to return with a cargo was the brig *Leonora*, which arrived in 1902 with 2,900 barrels of oil and a quantity of hides. In 1900 the schooner *Robert S. Graham* brought in 2,600 barrels of oil and 70 hides, the oil selling at 38 cents per gallon and the hides at \$2 cach. In 1898 the bark *Swallow*, of Boston, returned with 2,000 barrels of oil, the product of 4,000 sea-elephants secured during the three months of the summer of 1897–98.

According to Capt. James W. Budington, of Groton, Conn., to whom we are indebted for most of the subjoined data relative to methods of capture and of oil-rendering, sea-elephant blubber is somewhat whiter than whale blubber, and ranges in thickness from 1 to 8 inches, according to the size and condition of the individual. It is thickest on the males, especially the "March bulls," from the neck of which 10-inch blubber has been secured. On the cows the thickness is from 2 to 3 inches and on the pups it is much less.

Much variation exists in the yield of oil from sea-elephants. The quantity secured from the March bulls taken shortly after they land is very large, amounting sometimes to 220 gallons from a single individual. Only a small number of this variety is secured. The November bulls yield from 100 to 120 gallons each early in the season, but after remaining on the shore for months, abstaining from food, they become emaciated, and yield scarcely more than 30 gallons. The product from females and pups is much smaller, some of the pups yielding only 4 or 5 gallons, especially when the season is well advanced, thus

greatly reducing the average take, which probably does not exceed 12 or 15 gallons to each individual throughout the season. The cargo of 2,000 barrels secured by the bark *Swallow* in 1898 represented an average yield of 15.75 gallons per individual. Another cargo of 600 barrels, secured late in the season when the animals were in poor condition, represented the capture of 2,000 individuals.

The hunters endeavor to arrive at the islands as soon as the seaelephants come ashore, usually the early part of November. The animals are found in herds or pods varying in number from 20 to 300 or more each, the favorite resort apparently being the numerous mud puddles. The largest and fattest are selected for killing, females and pups being unmolested if a sufficient number of large bulls is obtainable. The bulls are sometimes of enormous size, frequently 16 feet or more in length and 12 feet in circumference. The females are very much smaller, probably one-third the size of the bulls, but generally they are fatter for their size and their blubber is somewhat more yellowish. A number of seals of various species, especially the leopardseal, are frequently met with and are driven out and slaughtered when sea-elephants are scarce; otherwise they are not molested, as they are not nearly so fat as the sea-elephants. Rifles and lances are the weapons commonly employed in the slaughter.

After killing a sufficient number the skin is roughly and quickly gotten out of the way and the blubber taken off in horse-pieces of suitable size for handling, say about 18 inches wide and 2 feet long, or less, this varying according to the thickness. The horse-pieces are strung on a pole and carried down to the shore, 15 or 20 making a good load for two men. At the shore the pieces are strung on rafttails or ropes, 18 or 20 feet long, and towed to the ship. The long immersion in the water soaks off the sand and blood and cleanses the blubber.

The oil is extracted in much the same manner as in the whale fishery. The blubber is lifted on deck, cut into strips about 2 inches wide, and these are minced or partly cut through at intervals of about 1 inch and placed in try-pots, precisely as in the case of whale blubber. The cooking is only slight, much less than applied to the whale blubber, being continued for only about 15 minutes. The fuel consists of the dry scrap, supplemented with wood procured on the islands. After cooking for about 10 or 15 minutes and dipping off all the oil on the surface, the scrap is placed in a receptacle and subjected to considerable pressure, in the manner customary in the right-whale fishery already described. The oil does not run as freely from the blubber as whale oil; especially is this the case with the fat of the pups, which is fine-grained and "milky." Occasionally the oil is tried out on shore in a manner similar to that aboard the vessel, the try-works being erected near a running stream wherein the blubber may be washed free from sand and blood.

The product from all the southern islands from 1803 to 1900,

inclusive, amounted to upward of 242,000 barrels, or 7,643,000 gallons, worth \$5,420,000, apportioned as follows:

| Decade ending June 30— | Barrels. | Decade ending June 30 | Barrels. |
|---------------------------|----------|--------------------------|--|
| 1810. | 2,500 | 1860. | 62,754 |
| 1820. | 9,000 | 1870. | 48,783 |
| 1830. | 9,500 | 1880 | $ \begin{array}{r} 34,015 \\ 8,150 \end{array} $ |
| 1840. | 23,000 | 1890 | |
| 1850 | 38,000 | 1900 | 6,300 |

This oil is classed as whale oil and has been included in the product of that article, as shown on page 204, although it is usually sold for 3 or 4 cents per gallon more than the latter. The process of refinement is precisely the same as in case of whale oil, the foots yielded amounting to 5 or 6 per cent of the original bulk. Its principal use has been in the dressing of morocco leather.

WALRUS OIL.

When the whalers entered the North Pacific, walrus were found in great numbers, but were not disturbed, owing to the abundance of cetaceans. At times when whales were not to be found and many walrus were met with, a number of these were killed and the blubber tried-out, and this practice extended with the increasing scarcity of whales. About 1863 the northern whalers began to make a business of taking walrus during the first part of each season, some vessels securing upward of 500 barrels. Mr. A. Howard Clarke estimated that, during the eleven years ending in 1880, 1,996,000 gallons of walrus oil were secured by the whaling fleet in the North Pacific, the value of which was about \$1,000,000.^a The hunt was carried on with much waste. It is stated that on one occasion 1,600 walrus were killed on a sand bar in one day, and the whole number were washed into the sea by an unusually high tide and thus lost. Since 1880 the quantity secured has decreased, and at the present time not more than 100 walrus are obtained annually by the entire North Pacific fleet, representing an oil product of less than 2,000 gallons.

The blubber of walrus averages 2 or 3 inches in thickness, and usually it is is not detached from the skin until after the removal of the latter from the carcass. In case the hide is to be saved for tanning, the pelt is placed on a flensing board or platform, skin-side down, and the blubber is cut off in irregularly shaped horse-pieces of 10 or 15 pounds' weight each. During the height of the Pacific walrus fishery the hides were not used, and then the skin and blubber were removed from the animal in horse-pieces of convenient size, say about 10 by 14 inches, and these were separated aboard the vessel.

The horse-pieces are next prepared for the try-pots. They are placed on the mineing-horse and scored or mineed precisely in the manner described in the treatment of whale blubber. The cooking must be

[&]quot;The Fishery Industries of the United States, Sec. V, Vol II, p. 318.

slow, the pot being well spaded during the boiling to prevent the blubber from sticking and burning to the bottom or side.

The individual yield of oil varies considerably, walrus being much fatter in some years than in others. But in general it is small in proportion to the size of the animal, an individual weighing 1,500 pounds yielding only as much blubber as a seal of 600 pounds. An old bull weighing 2,500 pounds might yield 600 pounds of blubber, but it is seldom more than 450 pounds, and the average for the entire catch is probably not in excess of 200 pounds. Nor is the blubber as rich in oil as is that of the seal, 100 pounds. Nor is the blubber yields about 114 gallons. In 1869 the ship *Progress* secured 565 barrels of oil from 700 walrus, an average of 25.42 gallons each. This was considered an extra good yield. One thousand walrus secured by the ship *Onward* in 1874 yielded 600 barrels of oil, and 2,000 taken by the *Mercury* in 1877 produced 1,100 barrels of oil.^a

Walrus oil is usually of a yellowish color, with greater fluidity than seal oil, and has a specific gravity of 0.925 at 59° F, according to Brannt. It is more difficult to refine than the oil of the right whale. Although classed roughly as "whale oil" in the United States, it is usually kept separate from the oil of the right whale and sold for 2 or 3 cents per gallon more than the latter. It is stated that the product in the fisheries north of Europe is generally mixed with and sold as seal oil.

OIL FROM SEA-LIONS AND FUR-SEALS.

The blubber of the sea-lion is from 1 to 4 inches thick, and that on each individual yields from 6 to 20 gallons of oil. Thousands of barrels of this oil were formerly secured along the coast of California, but owing to the decrease in number of these animals, comparatively little is now prepared. It is somewhat inferior to sea-elephant or walrus oils, but much better than fur-seal oil.

A number of years ago when whale and seal oils were quoted above a dollar per gallon, there was some sale in this country for oil prepared from the blubber of the fur-seal; but owing to the small quantity available, the cost of production, and the technical inferiority of the product, there has been no market for it for many years. The blubber may average $1\frac{1}{2}$ inches in thickness, varying according to the time the animal has been on shore. The oil is of a yellowish-brown color, gummy, and possesses an offensive odor. According to the terms of the lease of the fur-sealing rights on the PribioI Islands to the North American Commercial Company, the United States Government is entitled to receive 50 cents per gallon for all fur-seal oil produced there. This is in excess of the market value of the article, leaving nothing for the cost of production and transportation, and, needless to state, there is no revenue whatever from this item.

OIL FROM LIVERS OF COD AND RELATED SPECIES.

SOURCES OF SUPPLY.

Cod oil is obtained from the livers of several species of fish. In its pure state it is obtained from the livers of cod only, but those of haddock, pollock, hake, cusk, ling, and even shark and dog-fish are also used. The last two, however, are not generally recognized as cod-liver oil sources, but are used mainly for purposes of adulteration. In the trade the term "cod-liver oil" is used in a restricted sense, applying to the best quality of oil made from choice fresh cod livers and intended for medicinal purposes; all other oil manufactured from livers of cod and related species, not of quality fitting it for medicinal uses, is designated as "cod oil" or "curriers oil."

Cod oil is of comparatively recent development as an article of commerce, although it was used locally previous to the nineteenth century. On account of the ease with which whale and seal oils could be secured, cod oil was not in great demand for technical purposes until after the beginning of the nineteenth century. There is nothing to indicate that in the early cod fisheries on the American coast the livers were utilized to any great extent for oil-rendering, and the same is true of the early fisheries prosecuted in the seas north of Europe. The small demand for medicinal and for technical purposes was readily supplied by a few fishermen of economical and industrious habits, but their output fore only a small proportion to the total quantity obtainable. Curriers used a small quantity, and some was employed on fruit trees for destroying insects and fungous growth.

Early in the nineteenth century the production of cod oil became quite general on the New England coast. The livers were placed in butts and permitted to decompose, and the oil exuding therefrom was dipped off from time to time. Not only was this done by the fishermen who landed their catch ashore each night, but also by the "bankers" who carried butts and barrels for the purpose. As the tanning industries developed, the output of cod oil increased, and by 1845 practically all the livers secured were rendered into oil. The output, however, did not keep pace with the demand and during the sixties the price went up to \$1.25 per gallon. Mr. Eben B. Phillips, of Swampscott, was one of the pioneer dealers in this product and amassed a fortune in the business.

Gradually other substances were introduced as materials for dressing leathers, especially sod oil, degras, and compound greases, the cheapness of which has greatly affected the market for cod oil. The substitution of machine stuffing for hand stuffing in leather-dressing and the introduction of chrome tannage have also reduced the demand. However, the market for medicinal oil has constantly increased up to the present time. As a result of these combined uses, the rendering of the livers into oil is almost coextensive in point of territory with the prosecution of the cod fisheries. The only exception is in certain market fisheries where the men do not have time to handle the livers properly.

The market price of medicinal oil frequently falls so low that it pays the manufacturer better to prepare only low-grade oil for leathercurrying, soap-making, and the like. The common oil is, of course, turned out at much less cost than the white, odorless, medicinal variety. The stearin, which is worth comparatively little and forms a considerable portion of the oil, need not be removed from the manufacturing grade. The use of the expensive refining plant required for medicinal oil is also obviated. And, finally, there is a very considerable saving in the cost of packing, as the ordinary oil is shipped in old petroleum barrels, while for the finer grade expensive new casks or metallic drums have to be provided. For several seasons there was a large overproduction of low-grade medicinal oil, and three years ago it sold in New York as low as 50 cents per gallon. Curriers' oil does not often sell for less than 30 cents per gallon, and the demand for it is fairly constant.

The principal sources of cod-liver oil are the coast of North America from Labrador to Cape Cod, Norway, Scotland, Iceland, the Pacific coast of the United States, and, during recent years, Japan. On account of its greater value, efforts are made on all these coasts to produce the light oil for medicinal purposes; but in most sections, on account of unfavorable natural conditions, only dark or low-grade oils are practicable. Medicinal oil is prepared chiefly on the coast of Norway and to a limited extent on the Massachusetts, Maine, Nova Scotia, and Newfoundland coasts.

Owing to the favorable conditions under which the cod fishery is there prosecuted, Norway ranks first among countries producing medicinal oil, the annual product amounting to about half a million gallons. The fishing-grounds are concentrated and situated very near the coast, so that the fish are landed in quantities within a few hours after capture and before decomposition of the livers has set in. Furthermore, the temperature during the fishing season is very low, being close to the freezing point, and this tends to retard putrefaction. In no other part of Europe are the conditions favorable for producing medicinal cod-liver oil. A large quantity of low-grade or curriers' oil is also produced in Norway, amounting probably to as much in bulk as the medicinal oil.

In Newfoundland much attention has been given to the production of medicinal oil, the manufacturers endeavoring to make it as near like the Norwegian product as possible. Freezing machines were introduced and a considerable quantity of white, odorless, and noncongealing oil was made. The general experience, however, was that the difference in market value of the medicinal and the trade oils was not sufficient to warrant the extra care and the additional expense. At present comparatively little medicinal oil is produced in Newfoundland. The livers are mostly all converted into curriers' oil, resulting in an annual output of about 1,100,000 gallons.

The situation in Nova Scotia is pretty much the same as in Newfoundland, although much less oil is produced, the annual output probably amounting to about 20,000 gallons of medicinal oil and 250,000 gallons of curriers' oil.

The bank fisheries of America are situated too far from the land to permit the use of the livers in making medicinal oil; but the shore fisheries during autumn and winter, when the spawning fish visit the coast, furnish good material for that purpose, resulting in the preparation of about 25,000 gallons each year. Much of this is of superior quality, and unsurpassed for color and pleasantness of odor and taste. The livers taken in the bank fisheries are practically all used in preparing currièrs' oil, the total annual product of which is about 450,000 gallons.

Considerable cod oil has been exported from Japan for medicinal purposes, but that received in this country has not found favor with the wholesale druggists and has usually been sold for currying. The first shipment of 200 cases, made in 1889, sold at 35 cents per gallon. We have no data bearing on the cod-oil output in Japan, but with an annual catch of 7,000,000 fish it probably does not exceed 100,000 gallons.

The entire product of cod oil is estimated as follows: Norway, 1,200,-000 gallons; Newfoundland, 1,100,000 gallons; Dominion of Canada, 300,000 gallons; United States, 475,000 gallons; Japan and all other countries, 450,000 gallons, making a total of 3,525,000 gallons of all varieties of oil produced from the livers of cod and related species. Of this quantity about 650,000 gallons represent the output of medicinal oil, and the remaining 2,875,000 gallons is curriers' oil.

DESCRIPTION OF LIVERS AND THE RESULTING OILS.

The following description of livers and the account of rendering them into oil are the results principally of an inquiry made by the writer on the New England coast in October and November of 1901. Most of the oil factories were visited and many of the principal fishermen were interviewed. The writer is especially indebted in this connection to Mr. A. W. Dodd and Messrs. George J. Tarr & Sons, of Gloucester, and to Messrs. Geo. H. Leonard & Co., Mr. John B. Baum, and Mr. F. F. Dimick, of Boston.

Normal cod livers in good condition are of a cream color, uniform texture, and very soft, so that the finger may be readily pushed quite through them. Lean livers are frequently found. These are tough and dark in color, the toughness and darkness increasing with the degree of leanness, the color finally reaching a dark brown hue. Lean livers furnish very inferior oil, as well as only a small quantity. A certain percentage of the livers are diseased. This condition is usually evidenced by a greenish color or by the presence of colored spots, which increase in size and number as the disease advances until the entire organ is affected. Diseased livers are never used in the preparation of medicinal oil, but are freely utilized in making curriers' oil. The size of the livers varies considerably, but averages about 12 inches in length and $2\frac{1}{2}$ inches in thickness in the center, the weight being somewhat over half a pound. Some livers weigh only $1\frac{1}{2}$ ounces each, and an instance is recorded by Dr. F. P. Moller of one taken in the Lofoden fishery which weighed 11 pounds, its length being 43 inches and its greatest thickness $6\frac{1}{2}$ inches.

Considerable difference exists in the size, shape, and general appearance of livers of the cod family. Cod livers are elongated, with the large end near the dorsal fins and the small end toward the tail. Haddock livers are much shorter than those of cod, and have little frills or scallops on the edges, whereas those of cod are smooth. Haddock and pollock livers are of a cream color, similar to those of cod, while cusk and hake livers are of a light straw color. The livers of all *Gadidæ* are usually mixed together by the fishermen, but in the season when any particular species is abundant the livers of that variety are kept separate. On the New England coast of the United States cod livers predominate during the coldest months and pollock are taken mostly in October and November.

In the United States fisheries livers represent about 33 per cent of the weight of the fish, and they yield about 40 per cent of their weight in oil; consequently 100,000 pounds of fish yield about 180 gallons of oil. On an average, from January to June, 1,000 pounds, dressed weight, of cod yield about 1 bucket, or 24 gallons, of livers, and during the latter half of the year the yield increases to 4 gallons per 1,000 pounds of dressed fish. A bucket of these livers yields 5 or 6 quarts of oil on an average throughout the year, except that in the spring the product is sometimes reduced to about 3 quarts to the bucket of livers. The yield of hake livers per 1,000 pounds of fish is somewhat larger than in case of cod, but the quantity of oil secured from a bucket of livers is about the same. Haddock yield best from October to December, and during the spring and summer the result is small, sometimes not over 11 quarts to the bucket. On account of the small yield and the conditions surrounding the haddock fishery, only about 15 per cent of the livers of that species are saved in the New England fisheries At present pollock do not yield so much as cod, averaging about 5 quarts to the bucket of livers throughout the year; but previous to ten years ago on the New England coast they usually yielded 7 quarts of oil in the fall.

In the Lofoden fishery, according to the official returns, ordinarily 20 to 30 livers are required to produce 1 gallon of medicinal oil. During some seasons the livers are quite fat, and 8 to 12 are sufficient;

but when they are very lean, as was the case in 1896, for instance, from 36 to 56 are required for 1 gallon of oil. In that fishery the livers are fatter at the beginning than at the end of the season. They average about 55 pounds to the 100 fish; but during the years when they are unusually lean it is much less, as in 1883, when the average weight of 100 livers was only $12\frac{1}{2}$ pounds. Usually at the Lofoden Islands 250 to 1,100 cod give 1 barrel of livers, and 2 barrels of livers yield 1 barrel of oil; but in 1883 from 700 to 1,100 fish were required for 1 barrel of livers, and 4 or 5 barrels of those were necessary for 1 barrel of oil. Aside from the benefits accruing from the fatness of the livers, anything gained in quantity is always lost in quality in the preparation of medicinal oil.

While it is somewhat difficult to distinguish among the oils made from the livers of the various members of the cod family, yet ordinarily there are certain distinctive characteristics apparent to the skilled oil-refiner. Cod oil is of a greenish yellow color and usually has less pressings or foots than any of the others. Hake oil is almost white, but that made from hake taken on certain grounds has a pinkish color, which may be removed by filtration through a mineral earth. Pollock oil is distinguished by a slightly bitter taste and has a faint reddish cast. Its weather-test is rather lower than that of cod oil, especially when it has been slightly overcooked in the rendering.

Oil extracted from perfectly fresh cod livers is light and odorless. and, owing to its extensive use in medicine, is known as medicinal cod oil or "cod-liver oil." According to the extent of decomposition of the material before the extraction of the oil, the color ranges through all shades of vellow and brown to very dark brown, this color being attributed to the decomposition of the hepatic tissues and fluids. These dark oils are of two general grades; one, the brown, which is inferior to the light-brown or medicinal oil, but is frequently used for such; and the other, the dark-brown or curriers' oil, is the poorest grade prepared, and is exclusively used for technical purposes. Probably it would be better to say that there are two principal varieties of oil, the medicinal and the curriers', and that unusual market conditions may result sometimes in the employment of the poorest of the medicinal oil for technical uses or the best of the curriers' oil for officinal purposes.

The medicinal value of cod-liver oil was known centuries ago among the Laplanders in northern Europe, the descendants of the Norsemen in Iceland, and the Eskimos in Alaska. The use of the oil gradually extended in Europe during the eighteenth century, being a popular home remedy among many seacoast communities and used empirically by physicians. Percival and Bardsley in 1782 recommended its use in cases of gout and chronic rheumatism. In 1841, J. Hughes Bennett, of Edinburgh, published a pamphlet on its medicinal qualities, strongly recommending it in many cases, and this had much to do with the general introduction of the oil as a medicine in England and America. From that time to the present it has held a prominent place in the confidence of physicians, and is regarded as a remedy of the highest value in diseases which are marked by malnutrition, pulmonary tuberculosis furnishing the most frequent occasion for its employment.

Few subjects connected with materia medica have provoked so much discussion as the comparative merits of the light and the dark grades of cod-liver oil. Formerly, the brown oil was considered superior in efficiency to the paler sorts, and was generally favored for medicinal purposes. In recent years, however, chemists have claimed that analysis does not reveal any substance in the dark oil which would account for greater beneficial activity than the paler grades are supposed to possess. While many physicians yet recommend the brown oil, the drift of public opinion seems to favor the pale oil, and certainly it is more popular with the patients. A discussion of these rival claims is beyond the scope of this paper. For information on the subject reference is made to A. Gautier and L. Morgues' *Les Alcaloides de l'Huile de Foie de Morue*, Paris, 1890, and to F. P. Moller's Cod-Liver Oil and Chemistry, London, 1895.

PREPARATION OF MEDICINAL OIL.

On account of its greater value, it is generally desirable to convert the livers into medicinal rather than curriers' oil. For this grade the livers must be perfectly healthy and fresh, all diseased, lean, or slightly decomposed ones being rejected. On account of the necessity for having the material perfectly fresh, it is impracticable to manufacture good medicinal oil during the warm months, and even in cold weather the sooner the extraction of the oil is begun the better the grade secured. Furthermore, it is desirable that the livers should be from cod only, those from other species being excluded. This, however, is not the uniform practice, and the livers of haddock, hake, cusk, etc., are sometimes thrown in with those of cod. It does not appear that American manufacturers are any more prone to this adulteration than those of other countries. Possibly oil from other livers may be equally as efficient as cod, yet until that fact is demonstrated beyond a doubt those should be rejected.

On the New England coast of the United States, the best medicinal oil is made from livers collected from the shore fishing boats, which land their catches almost daily, and thus deliver them in fresh condition. From May to October only a small amount of the best oil can be made, because of the scarcity of fish along shore during that season and the danger of the material putrefying before reaching the oil factory. From October to May the shore fishermen carefully save the livers in clean barrels, and if landed within a day or two they are sold for making medicinal oil, but if softened or damaged in any way they are used only for curriers' oil.

222 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

Second only to the careful selection of the livers is the observance of perfect cleanliness in the entire process of rendering the oil. The livers are thoroughly cleansed from blood and other impurities by washing in several waters, and the gall sacs and attached membranes are removed. Throughout the entire process of expressing and refining the oil, all tanks, receptacles, and the like are kept free from putrefying texture. Some oil-renderers chop the livers into small pieces for the purpose of securing a greater quantity of oil, but this is by no means the general practice.

There are two general methods of cooking the livers, viz, (1) by wood or coal fire under a water bath, and (2) by the use of steam. The first-named is the oldest in use and is also the most economical where the quantity of material to be rendered is small. Two metallic receptacles or pots are provided, one, in which the livers are placed. fitting loosely in the other, with 2 or 3 inches of space between, and the larger one set into a furnace so that a fire may be built beneath. The space between the two receptacles is filled with water during the process of cooking, and this is renewed as required. A fire is built in the furnace and the water brought to a boiling point, thus imparting a moderate heat to the contents of the pan. In order that the cooking may be expeditious the pan should be small, holding not over 50 or 60 gallons. Furthermore, it should be narrow, for greater ease in stirring and to minimize the oxygenizing of the oil. Owing to the cheapness of this apparatus it is quite popular with those who try-out only a small quantity of oil.

In the second method of cooking, steam-jacket kettles are used, the steam-chest being provided with a self-acting safety valve by which the pressure can be controlled and regulated. Within the kettle there is usually a stirring apparatus operated by steam power. By means of this apparatus the cooking may be performed much more expeditiously than with the former one, as any desired temperature may be secured and uniformly maintained.

In order to prevent, so far as practicable, the formation of hydroxylated compounds, the alleged cause of the unpleasant eructations or gastric disturbance from which many persons suffer after taking the oil, there was introduced in Norway in 1892 an apparatus for its extraction without permitting oxidation to take place. This apparatus is so contrived that the air can be completely excluded from it during the whole operation, the process being conducted in a current of carbonic acid gas from the moment the livers are placed in the apparatus until the oil is sealed up in the market receptacles.

Whatever process of cooking may be adopted, it is desirable that the oil be forced out of the hepatic cells in a short space of time and by a moderate degree of heat only. The length of time usually allowed for cooking is from 2 to $3\frac{1}{2}$ hours, and at no time should the temperature execed 200° F. The duration of the cooking process is an item of great importance in the preparation of medicinal oil, and on it is dependent in a large measure the quality of the product. In order to get the largest possible amount of oil, some producers cook the material entirely too long, notwithstanding that beyond a certain point anything gained in quantity is at great sacrifice of quality. In producing a choice grade of oil, the livers must not be exposed to heat any longer than absolutely necessary.

The longer the cooking is continued, the greater the quantity of acids and decomposed albumen extracted from the hepatic tissues. These substances render the oil strong and unpalatable, and detract from its appearance. Further, the longer the livers are exposed to heat, the more oxygenized the oil becomes, making it irritative to the stomach and causing disagreeable eructations. For the production of the clearest and lightest medicinal oil, the livers should not be exposed to a greater heat than 160° F., and that only for about 45 minutes. This, however, is not feasible because the quantity of oil produced in that case would be too small to make the business profitable. The time must, therefore, be extended as far as practicable without detracting too much from the quality. But in order to produce a first-class medicinal oil, the length of the cooking should on no account exceed $2\frac{1}{2}$ or 3 hours, provided the capacity of the liver receptacle does not exceed 50 gallons.

On completion of the cooking process, the mass of livers and oil is allowed to cool. The oil rises to the surface and is drawn off and filtered. The liver magma is subjected to pressure and yields a quantity of dark oil suitable only for curriers' use. The residuary mass of hepatic tissues is dried and used for fertilizing purposes. Its market value in Gloucester and Boston was formerly \$6 or \$8 per ton, but at present it is only about \$3 per ton.

Filtering the medicinal oil is accomplished by running it through a box fitted with several straining frames covered with cloth of successive degrees of fineness and with a tap at the bottom through which the oil can be drawn. Or the filter may consist of one or two light canvas bags fitted inside of a white moleskin bag with the smooth side out. But in filtering the dark oil, it is better to run it through charcoal.

In the process of refining, the medicinal oil is placed in small receptacles, as 5-gallon cans, and refrigerated either naturally in cold weather or by means of ice and salt, as already described in the process of refining sperm oil. When thoroughly chilled and granulated the congealed oil is compressed through cotton or canvas bags holding about 4 gallons each, for the purpose of extracting the foots, white pressings, or stearin. Two or three bags are placed regularly upon a substantial wooden platform or table provided with grooves for conducting the outflowing oil to a receiving tank. On this row of bags there is laid a thin iron plate or slab, then another layer of bags, and so on, layer after layer, until 15 or 20 bags have been piled up. Heavy pressure is then applied and continued 10 or 12 hours, when practically all the oil drains from the bags, leaving behind an unctuous mass of the consistency of tallow or butter, composed of nearly pure stearin, with a small quantity of débris and fibers. The quantity of stearin removed depends on the temperature at which the congealed oil is pressed. At the usual temperature of 28° to 30° F., about 14 pounds are removed from each gallon of crude oil, the latter weighing about 7 $\frac{1}{2}$ pounds. The stearin is sold at 5 or 6 cents per pound and is used by soap- and candle-makers and as a tallow substitute in leather-dressing.

Medicinal cod-liver oil should be exposed to the air as little as possible during the whole process of extraction, filtering, and pressing; and as soon as the last operation is completed, it should be placed in shipping packages and stored in a cool place until marketed. This oil has a greenish tint, is almost tasteless and odorless. For the purpose of making the oil lighter in color, it is sometimes bleached by exposing it in a thin layer to the sun's rays for an hour or more. Bleaching medicinal oil is an objectionable process, resulting in no particular benefit, and, on the contrary, is productive of much harm when long continued.

The style of the package in which medicinal oil is placed is of much importance. Since cod oil readily acquires the flavor of wood and becomes discolored thereby, glass or metal receptacles are preferred. Tin is much the best material when glass is not used. The Norwegians use tin-lined barrels. When wooden barrels are employed, white oak is preferable to other varieties.

During recent years many manufacturing pharmacists have prepared cod-liver oil in such a manner as to overcome the disagreeable flavor and the even more objectionable gastric disturbance which so frequently follows its use. These products are mostly in the form of emulsions, gelatinous capsules, with sirups, creams, jellies, etc.

Furthermore, some pharmacists remove the so-called "active principles" in cod-liver oil, the oil itself being subsequently used for technical purposes. These "active principles" are extracted by means of an alcoholic menstruum, then concentrated by evaporation and dissolved in wine. They are placed on the market under various In some factories the fresh livers, rather than the proprietary names. oil, are used in manufacturing the "active principles," since the latter are alleged to occur in far greater abundance in the liver tissues than in the oil. According to an account given by the proprietor of one of these preparations, the livers are thoroughly minced in a steam-power chopping-machine and macerated for several days in large stirring machines of special design, a menstruum being employed consisting of diluted alcohol containing a small quantity of citric acid. The extract is then drawn off and concentrated in vacuo at a temperature of 40° F. When the liquid is reduced to about the consistency of

extract of beef, it is removed from the vacuum pan, assayed for alkaloidal contents, and then dissolved in wine in proper proportion to represent the "active principles" contained in one-fourth its bulk of cod-liver oil.

Only about 10 per cent of the cod-liver oil consumed in this country is produced in the American fisheries, the great bulk of it being imported from Norway. As already shown, the product of medicinal oil in the United States fisheries is only about 25,000 gallons each year, whereas the imports usually exceed 200,000 gallons annually, and in some years exceed 500,000 gallons.

The following summary, showing the total quantity and value of cod-liver oil imported for consumption into the United States during a series of years, is compiled from the United States customs returns:

Statement of the quantity and value of cod-liver oil imported into the United States during a series of years.

| Year ending June 30— | Gallons. | Values. | Average value per gallon. | Year ending June 30— | Gallons. | Values. | Average value per gallon. |

PREPARATION OF COD OIL FOR TECHNICAL PURPOSES.

The methods of extracting cod oil for currying and other technical purposes does not differ essentially from the extraction of medicinal oil, the principal difference being the use of all livers secured, the absence of extreme cleanliness, and the greater putrefaction or the more extensive cooking of the material. Considerable common oil is also expressed from the livers cooked for medicinal oil after the latter has been dipped or skimmed off.

The original method of extracting cod oil, and the most common one at the present time, is by putrefaction. In the Grand and the Western banks fisheries, during the process of dressing the fish, the livers are collected and placed in liver-butts. These butts are characteristic of vessels engaged in a salt-fish trip; in the market fishery for cod, haddock, etc., their place is taken by upright barrels or gurry kids. There are two liver-butts on each vessel; they consist of large casks, with a capacity for about 150 gallons each, mounted horizontally on skids immediately in front of the house and lashed securely to the deck. On the top, in the bilge of each cask, there is a large square opening, covered with a piece of tarpaulin securely fastened at one

F. C. 1902-15

end, through which the livers are dropped into the cask. As the oil cells in the livers are broken by decomposition and by their constant churning with the rolling of the vessel, the oil rises to the surface, and is bailed off from time to time to make room for fresh livers. The oil dipped or bailed off, known as "sun-tried oil" or "top dippings," is placed in barrels, while the refuse blubber remains until the vessel reaches port, when it is boiled to extract the remaining oil.

The "sun-tried oil" represents probably 20 to 40 per cent of the total quantity of oil produced. It is superior to that rendered by cooking, being heavier bodied, and does not chill so quickly, the quantity of foots being much less. The oil first obtained from the butts is of a light yellow color, and formerly was used to some extent for medicinal purposes. As putrefaction advances, the color deepens to a brownish shade, and that extracted by cooking the decomposed livers ashore is very dark, with a greenish fluorescence in reflected light. In small quantities it shows a brown color, and therefore is known as brown oil. None of this oil is used for medicinal purposes, owing to its strong odor and flavor and the abundance of decomposed tissue contained in it. The market fishermen, who return to port every two or three weeks, save the livers and sell them to the oil-merchants at 25 or 30 cents per bucket of $2\frac{1}{2}$ gallons each.

Of the several grades of cod oil used for technical purposes, the best is that made from livers taken in the Grand Banks fisheries; this is known as "Newfoundland cod oil" and sells for about 2 cents per gallon more than "domestic cod oil" made from livers taken on Western and Georges Banks. "Straits oil" and "bank oil" were formerly well-known grades of cod oil, but these are now made entirely from menhaden. The low grades of cod oil are strained or filtered in the same way as the medicinal oil, 100 gallons yielding 15 or 20 pounds of foots, worth about 4 cents per pound.

Cod oil is used for currying mostly in New York, Pennsylvania, Ohio, Michigan, Illinois, and Wisconsin, only about 20 per cent being used in New England. Some of the best quality is exported. Small quantities are also used for soap-making and in various compounds.

The following table (based upon the closing quotations each week for prime domestic oil, as contained in the New York trade journals) shows the lowest and highest selling prices for cod oil for technical purposes in the New York market during each year from 1891 to 1902:

| Year. | Price per gallon. | Year. | Price per gallon. | |
|----------------------|---|-------------------------|---|--|
| 1891 1892 1893 | \$0.32 to \$0.43 .37 .30 .36 .39 .28 .38 | 1897 1898 1899 | \$0.24 to \$0.30 .28 .35 .32 .34 | |
| 1894 1895 1896 | $ \begin{array}{cccccccccccccccccccccccccccccccccccc$ | 1900. 1901. 1902. | $ \begin{array}{cccc} .30 & .37 \\ .31 & .38 \\ .33 & .39 \end{array} $ | |

OIL FROM LIVERS OF SHARKS AND RELATED SPECIES.

The livers of various species of sharks and allied fish are suitable for oil-production, giving rise in some localities to important fisheries. The principal species used are the sleeper shark, otherwise known as the nurse, ground, or gurry shark (*Somniosus*), taken in northern waters from the Arctic seas southward to Massachusetts, Oregon, and France; the basking or bone shark (*Cetorhinus*), formerly quite numerous, but now taken to a less extent, north of Europe and on the coast of Peru, Australia, California, etc.; the oil shark (*Galeorhinus*), on the Pacific coast, especially in California, and the dog-fish (*Squalus*), distributed throughout both hemispheres. In addition to these, nearly every species of shark yields livers suitable for oilrendering.

The sleeper shark appears to be the most important species so far as oil-making is concerned. This is a large fish, individuals ranging in length from 12 to 25 feet. The livers yield from 12 to 50 gallons of oil each when taken in the autumn, but in the spring and summer they are almost worthless for oil purposes. On the New England coast this species is much less numerous than formerly, but it is reported in abundance on the Pacific coast of the United States.

During the autumn the taking of the sleeper shark is a somewhat important branch of the minor Icelandic fisheries, and it is also taken by the Russians off the Kola Peninsula. The most important fishery, however, is off the coast of Norway, and especially between Lofoden Islands and Bear Island, in depths of from 150 to 200 fathoms of water. The Norwegians employ small vessels of 20 to 35 tons, carrying about six men each, the season beginning the first of October and ending in February. The fish are taken by means of large, strong hooks baited with fish or salted seal blubber.

The basking shark, probably the largest of all sea fishes, has been taken very extensively for the oil contained in the livers, but owing to decrease of the species the quantity now secured is much reduced. This fish attains an enormous size, the prevailing length of fullygrown individuals being 30 to 35 feet. The liver is proportionally large, yielding ordinarily from 80 to 200 gallons of oil and occasionally as much as 400 gallons. Indeed, a yield of 600 gallons has been reported from a single individual, but this has not been satisfactorily established. This species differs from other sharks in not being voracious. Therefore it must be taken with harpoons rather than with baited hooks. There is said to have been quite an extensive fishery for it on the Massachusetts coast about the middle of the eighteenth century. According to Captain Atwood, writing in 1880, "Not more than half a dozen have been caught near Provincetown since 1810."

The basking shark is numerous on the coast of Peru and Ecuador,

228 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

and its capture gives employment to a large number of small vessels, manned by 6 or 8 men each. The American vessels fishing for humpback whales on that coast have occasionally engaged in its capture when whales were not in sight. Capt. George O. Baker, of New Bedford, reports that on one occasion in two days' fishing he secured 125 barrels of shark oil while on the lookout for humpback whales.

The method of taking this fish off the Peruvian coast, according to Captain Baker, is to approach it while it is lying motionless at the surface of the water and to fasten a harpoon in the top of the head forward of the eves, so as to hold the head up and thus prevent the fish from going down or "sounding," and then the boat approaches and lances it until it is quite dead. It is taken alongside the vessel, a hole is cut in one side of the abdomen, a strap inserted on either side of the incision and the tail hoisted up so as to raise the body somewhat out of the water. A man then enters the abdominal cavity and with a knife cuts out the liver in pieces. These are passed up on deck, minced, as in the case of whale blubber, and placed in the try-pots. After a sufficient length of time the cooked liver-pieces are removed from the pot, placed in a canvas or hempen bag, suspended from aloft, and permitted to drain. Nothing but the oil is saved. A considerable market for it exists in South America, where it is used principally as a body for paints for exterior surfaces. The price is usually 8 or 10 cents per gallon more than that of humpback oil.

The basking shark is taken occasionally on the California coast, the individual yield of oil there averaging about 125 gallons. The same species is also said to be taken in the waters of British India, being harpooned in great numbers by the fishermen of Karachi and other coastal districts.

The common dog-fish (Squalus) of the Atlantic coast and a similar species on the Pacific coast are the principal oil-yielding sharks in America. These fish range from 2 to 5 feet in length and from 5 to 15 pounds in weight. They are the great pest of fishermen, destroying nets, robbing fish from the trawls, and committing other depredations.

It does not appear that any important fisheries are organized especially for the capture of these fish, but many are taken incidentally in the shore and Georges cod fisheries, particularly during the spring, and the livers are extracted and thrown in the liver-butts along with those of other fish. The livers are generally of a bluish-gray color, shaped somewhat like those of cod or pollock and are very brittle, breaking readily when lifted.

In Boston and Gloucester dog-fish livers are sold at the same rate as those of cod and related species—viz, 25 to 30 cents per bucket of $2\frac{1}{2}$ gallons. The yield of oil during August, September, and October is about 6 quarts per bucket, but at other seasons it is much smaller.

Because of the small quantity secured, this oil is rarely kept separate from cod oil for currying purposes, and it sells for about the same price per gallon. A distinctive characteristic is its strong odor when warm, resembling that of ammonia; but this may be removed by proper refining. It is estimated that from 10,000 to 15,000 gallons of dog-fish oil are prepared on the New England coast annually, nearly all of which is combined with and sold as cod oil for currying purposes. Captain Atwood writes:^a

When I first began to go fishing, in 1810 to 1820, the dog-fish fishery was considered one of the most valuable fisheries that we had around the shore. They appeared here in the spring and were very plenty, and would last a day or two and then all would be gone. Then you would not see a dog-fish again all summer, but about the 10th or middle of September they came to us again, returning South. They would stay into November, and during that time the fishermen would get—a man and a boy-all the way from 8, 10, to 15 barrels of oil. Twenty-five years ago we would occasionally see dog-fish in the summer. The last fifteen years they have been here all summer. During the war they were plenty all summer, and the livers sold for \$1 a bucket, and now they are worth but 20 or 25 cents.

On the coast of Oregon, Washington, and British Columbia, large numbers of dog-fish are taken for conversion of the livers into oil. which finds a ready sale, owing to the high cost of other oils on that These fish are reported especially abundant in the vicinity of coast. Queen Charlotte Island, in British Columbia, where they are captured by the Indians. The livers of 100 dog-fish yield 6 or 8 gallons of oil, and the rest of the carcass is utilized for fertilizer. Not only is there an abundance of this oil produced for local use, but also much for export. As long ago as 1876, about 60,000 gallons were exported from Victoria, at a valuation of 40 cents per gallon.^b The present annual product is said to exceed 200,000 gallons. New York dealers have received some good samples which indicate a very low weather-test, but owing to the duty and freight rates little has come on the Eastern market.

Dog-fish oil has been used on the Pacific coast in competition with other oils with most favorable results, being "equal, if not superior, to oil supplied to Her Majesty's ships by the service, both for lubricating and lighting purposes."^c

Similar species of dog-fish are taken on the coasts of Norway, Chile, and elsewhere, the fisheries being confined to the summer months and the catch secured with nets as well as with hooks.

Along the Atlantic coast of the United States but little attention is given to the capture of sharks for economic purposes, notwithstanding the many species which occur there in comparatively large numbers. In several localities on the southern coast small fisheries are prosecuted during the winter months, for then the yield of oil is greatest. Among the species taken, other than those above mentioned, are the sand or yellow shark (Carcharias littoralis), which

229

^a Fishery Industries of United States, Sec. I, p. 674. ^b Report of the Commissioner of Fisheries of Canada for 1876, p. 346. ^c Fourteenth Annual Report of the Department of Marine and Fisheries of Canada for the year 1881, p. 214 of supplement No. 2.

230 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

attains a length of 5 feet, and yields from 1 to 2 gallons of oil; the leopard or, tiger shark, length from 10 to 25 feet, vielding 10 to 20 gallons of oil; the mackerel shark, also known as porbeagle or blue shark, measuring from 8 to 10 feet in length, and the liver yielding from 2 to 7 gallons of oil: the dusky shark (*Carcharhinus obscurus*), which attains a length of 10 feet; the hammer-headed shark (Sphurna zugæng), of 12 or 15 feet in length; the dog shark (Mustelus canis), 2 or 3 feet in length; and the thresher shark (Alopias vulpes). Some of the large sand and leopard sharks are difficult to secure and their capture gives considerable trouble. They are taken usually by means of harpoons or stout hooks and lines. When taken from a small boat at sea, immediately after the fish has been secured it is lanced to death, the belly is ripped open with a knife, the boat canted, and the large, slipperv liver pulled over the side into the boat, and then the carcass is discarded. Many of the smaller sharks are captured with menhaden, in purse seines, and are utilized at the menhaden fac-Owing to the damage which they do to the twine, the fishertories. men prefer to not set the seines around sharks, but it is difficult to avoid taking a few of them with the menhaden. It is estimated that from 7,000 to 10,000 sharks are captured annually by the menhaden steamers, all of which are converted into oil and fertilizer.

On the Pacific coast of the United States, especially in California, the oil shark (*Galeorhinus*) is utilized. It is 4 to 6 feet in length and weighs from 40 to 70 pounds, the yield of oil from the livers varying from two-thirds of a gallon to 1 gallon each. The fish are taken by means of hooks and lines when they enter the lagoons for reproductive purposes during the summer. The fins of this species are dried and sold for 12 or 15 cents per pound, the Chinese using them in soup-making. Other species of shark utilized on the Pacific coast are the shovel-nose shark, thresher shark, and the man-eater or white shark. The shovel-nose shark was taken extensively along the coast of Humboldt County, Cal., from 1858 to 1868, from 50 to 60 men being employed at times in the fishery. It is harpooned in deep water and taken by means of hand lines in shallow water. This species measures from 6 to 10 feet in length, and the liver of each individual yields 3 to 7 gallons of oil.

There are several species of skates, rays, etc., occurring on the United States coasts which are utilized to some extent for oil-production. Principal among these are the common skate (*Raja erinacea*), the prickly skate (*R. eglanteria*), the smooth or barn-door skate (*R. lacis*), the sting ray (*Dasyatis centrura*), the cow-nose ray (*Rhinop-tera bonasus*), etc. Many thousands of these are captured by the menhaden fishermen and utilized at the factories for conversion into oil and guano. Oil from the liver of the torpedo or eramp-fish (*Tetronarce occidentalis*), a large species, which at times attains a weight of 200 pounds, is said to be valued by the fishermen in the treatment of eramp and rheumatism.

Captain Atwood wrote in regard to the oil from the torpedo:

I used to go and look for them for their livers—for the oil. The oil is one of the best lamp oils that I ever saw. It has been used sometimes beneficially in cases of cramp. I got a gallon of oil from one liver. I do not know but I have seen a cramp-fish big enough to make three gallons of $oil.^{\alpha}$

The liver of the saw-fish (*Pristis*), numerous on the South Atlantic and Gulf coasts of the United States, yields from 6 to 18 gallons of oil. It is said that in British Guiana this oil is used for illumination and also for anointing the bodies of the inhabitants. The liver of the elephant-fish (*Chimæra*), which occurs in abundance on the California coast, is large and yields choice oil. This fish has a maximum length of 2 feet and weighs 6 or 7 pounds.

It appears from the above that the yield of oil from individual shark livers ranges from much less than 1 pint in case of the dog-fish and others to the 400 gallons procured from the basking shark. Other than the livers, the carcasses of sharks are slightly oleaginous, and are rarely ever utilized in oil-rendering, but they are of course useful for conversion into fertilizer. The method of extracting the oil from the livers is much the same in all cases. If they are large, they should first be cut in small pieces or minced, as is done with whale blubber. The pieces are then subjected to heat until the cells are thoroughly broken, when the oil is extracted by pressure or it is permitted to drain therefrom. In case the oil is to be used for medicinal purposes great cleanliness is observed, the livers being washed free from blood and the gall bladder removed. A quantity of water is placed in the kettle with the hepatic tissues and the whole boiled gently for an hour or two. On cooling, the oil floats on the surface and is dipped off and stored. It may be refined in precisely the same manner as cod oil.

According to Brannt, shark oils are distinguished as being the lightest of fixed oils, their specific gravities ranging from 0.870 to 0.880 at 59° F., so that a mixture with blubber or other fish oils can at once be recognized by the higher specific gravity. They are pale yellow and clear, remain fluid at 21° F., and contain very little stearin. They burn with a bright flame without carbonizing the wick. Brannt further states that they contain about the same constituents as cod-liver oil, but are richer in iodine. On account of their percentage of gall constituents the liver oils are readily distinguished from other fish oils.

Shark oils are largely used in tanneries, in steel-tempering, and in various compounds where it is desired to impart a low specific gravity. They are also valuable as a body for paints for out-of-door objects, as walls, fences, etc. In some localities certain kinds are used by medical practitioners, who consider them quite equal to cod-liver oil. In the drug stores of this country shark oil is occasionally found with a label suggestive of an oriental origin and recommending its use as an embrocation in numerous diseases.

^aNatural History of Aquatic Animals, p. 667.

MENHADEN OIL.

In speaking of fish oil in a restricted sense along the Atlantic coast of the United States, reference is made generally to that yielded by the menhaden (*Brevoortia tyrannus*), a member of the *Clupeidæ* or herring family, known locally by a score or more of names. This species occurs from Maine to Texas, the principal fishing-grounds being the bays and sounds from Maine to North Carolina, with the addition of the Texas coast during the last two years.

The extraction of menhaden oil differs from the preparation of other marine-animal oils in that the scrap or solid tissue remaining after the liquids have been removed is usually greater in value than the oil. Indeed, it was principally as a fertilizer that the menhaden was first utilized, the oil being extracted as an incidental product. Because of the greater value and importance of the scrap, the methods of manipulating the fish, extracting the oil, and the like are described in the second part of this report, relating to the preparation and utilization of fertilizers from fishery products. (See pp. 255–265.)

While small quantities of menhaden oil were prepared for domestic and local use previous to 1860, there was comparatively little marketed previous to the civil war. The first lot on the New York market sold at 75 cents per gallon and, its use giving satisfaction, the market price quickly advanced to \$1.40 in 1865, the highest figure ever realized. For ten years the menhaden producers sold their crude oil within a range of 50 cents and \$1 per gallon, resulting in great profit. This led to a large increase in the number of factories, the purchase of costly steamers and equipments, and a great overproduction.

The excess of production, a lack of cooperation among the factorymen, and competition with substitutes resulted in a gradual reduction of prices, until in the autumn of 1887 menhaden oil sold at 19 cents per gallon, which was much below the cost of manufacture. The necessity for protecting their invested capital led to concerted action among the producers and an attempt to bring about an agreement on prices and also a limitation of the fishing season. Many factories were closed and the vessels laid up, the owners preferring to keep them idle rather than to engage in unprofitable work.

The diminished extent of the output and a better understanding among the producers resulted in an improvement in prices, which finally reached 40 cents per gallon in the spring of 1893. Then, owing to unfavorable conditions, prices began to decrease until in the fall of 1896 crude northern menhaden oil was sold at 18 cents per gallon, the lowest price ever reached. Since 1896 the business has been conducted with much less competition and with greater economy by reason of improved machinery and increased facilities, and as prices have been somewhat higher a fair profit has been derived from the business by those whose invested capital is not greatly in excess of the value of their respective plants.

During the last thirty years the product of menhaden oil has averaged about 2,000,000 gallons annually. The largest yield was in 1878, when 3,809,233 gallons were produced, and the smallest in 1881, when the reported product was only 1,266,549 gallons. The following summary, compiled from the returns of the United States Menhaden Oil and Guano Association, shows the product for each year from 1873 to 1898, inclusive, and also the number of fish taken. For purposes of comparison, the average quantity of oil to the thousand fish in each year is also given.

Statement of the quantity of menhaden oil manufactured, the number of menhaden utilized, and the average quantity of oil to the thousand fish in each year from 1873 to 1898, inclusive.

Menhaden oil varies in color from clear straw, through amber and the various shades of brown to almost black, depending principally on the condition of the oliferous material when the oil is rendered. If

233

the fish are fresh, the resulting oil is usually clear, bright, and comparatively odorless and tasteless; and according to the extent of the decomposition the oil becomes darker in color until it approaches a very dark brown. However, this is not always the case, for perfectly fresh fish sometimes yield dark oil.

The standard grades recognized for crude oil are A, B, C, and D; these terms being synonymous, respectively, with extra light crude, light crude, brown crude, and dark brown crude. The bulk of the output is of A grade, and little D oil is now prepared except in the Southern factories.

In the process of refining, menhaden oil is first heated and then placed in barrels and chilled in the manner already described for whale oil, either by exposure during cold weather or by refrigeration. This chilling grains the oil, the thick parts collecting together and the limpid oil forming globules. The grained oil is then placed in bags made of coarse material, and these carefully arranged one above another in a press. On applying compression, the thin oil comes out first and the impurities and stearin are left behind. The oil is then placed in shallow vats or tanks, exposed to the rays of the sun and protected by a glass covering, where it remains for a day or two. It may also be clarified by treating it with caustic soda and acids, resulting in a short time in a clear, light-straw color.

The pressing of the oil in connection with its refinement may be done at a summer temperature, but in that case only a portion of the foots are extracted and the oil has a poor weather-test. The usual weather pressing during the summer yields 5 per cent of foots, and the oil stands a temperature of about 50° F. If pressed at a temperature of 32° to 35° F., the foots extracted represent about 10 per cent of the original bulk. The foots are used as a substitute for tallow in leathercurrying and also in soap-making, the market price approximating 3 cents per pound.

The products from refining menhaden oil are pressed extra light, pressed light, pressed light brown, pressed dark brown, bleached, extra bleached, oil foots or pressings, bleached oil foots, extra bleached oil foots, and menhaden oil soap. The first four grades of pressed oil are obtained respectively from A, B, C, and D grades of crude oil. A difference of about 1 cent per gallon exists between the prices of each of these consecutive grades of pressed oil. The pressed light is the standard grade, and when that sells at 30 cents per gallon the pressed extra light sells at 31 cents, the pressed light brown at 29 and the pressed dark brown at 28 cents per gallon. On the same basis the bleached sells at 33 cents per gallon, the extra bleached at 35 cents; and the same oils pressed at a low temperature sell for 1 or 2 cents more per gallon. A corresponding price for the unbleached foots is $\frac{21}{2}$ cents per pound; bleached foots, $\frac{31}{2}$ cents per pound; extra bleached foots, $\frac{4}{2}$ cents.

The names "straits oil" and "bank oil" were formerly applied to

certain grades of cod oil, but at present these refer, respectively, to B and C grades of pressed menhaden oil, gradual increase in adulteration having resulted in complete change of material.

The principal uses for menhaden oil are currying or filling leather, illuminating, paint-making, lubricating compounds, tempering, soapmaking, screw-cutting, wire-drawing, and cordage-manufacture, the first three consuming about 80 per cent of the total product. The light and extra light oils are generally employed in illuminating, lubricating, painting, and cordage-manufacture; the light brown for currying, and the dark oil for tempering and screw-cutting.

Large quantities of menhaden oil were formerly used by miners in safety lamps, but leather-currying has been the principal consumer during the last thirty years. Its use in steel works is of comparatively recent origin, and the steel industries now require many thousands of barrels annually.

It was as a substitute for linseed oil in painting that menhaden acquired its first popularity prior to 1865. The oil as then prepared was of very indifferent quality, the process of manufacture being comparatively crude, and much of the product would not now be considered marketable. On account of its being too highly recommended and all grades being sold for the purpose, considerable prejudice was soon created against it as a substitute for linseed oil. But with the improved methods of extraction and refining and with a better understanding of its limitations and technical qualities, these objections have been largely overcome. Its odor makes it undesirable for interiors and restricts its use to outside surfaces. According to Mr. A. H. Gill, its value for drying is somewhat less than that of linseed, but greater than that of poppy-seed, corn, cotton-seed, and sesame oils.

Menhaden stands the weather much better than linseed oil, especially when applied to tin roofs and ironwork. Owing to its glutinous nature, it is harder to apply than linseed oil, and consequently workmen do not always favor its adoption. This use of menhaden oil is now increasing and a single paint factory in New York City consumes 4,000 or 5,000 barrels annually.

If the oil is cleared from the foots by straining or pressing, cut with sulphuric acid of 45° strength in proportion of 1 gallon of acid to 50 gallons of oil, well stirred in and permitted to settle, and then washed down by a spray of cold water played on it, the acid and gluten are precipitated. Thus treated, menhaden makes a good substitute for linseed oil in mixing paints; it may also be used for leather-dressing and, mixed in equal proportions with paraffin and plumbago, makes a desirable lubricator.

The use of menhaden oil for illuminating purposes is confined to miners' lamps, especially in the coal mines of Pennsylvania and West Virginia. For this purpose it is generally combined with mineral or vegetable oils, the mixture giving better satisfaction than the use of menhaden oil alone. It is non-explosive and therefore much safer

236 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

than mineral oil. The luminous effect of refined menhaden oil has been found to be high with a relatively low consumption, as compared with petroleum.

The following treatment of menhaden oil in combination with other substances for painting purposes is recommended by Andes:^a

Into a wooden barrel are brought 144 liters of good vinegar, 6 kilograms of litharge, and 6 kilograms of zinc sulphate; then the barrel is rolled about for a long time, and the liquid then poured into 100 liters of fish oil. The mixture is well stirred, and then left at rest for twenty-four hours; when the clear oil is drawn off, seven-eighths of the original quantity is obtained. Fifty-four liters of linseed oil and 9 liters of turpentine are at once added. The liquid is left at rest for several days, and then drawn off. The residue is mixed with an equal volume of milk of lime, and used for painting wood and iron which are exposed to the air.

When whale and cod oils are scarce and high in price menhaden oil is extensively used as a substitute. Its chief competitors are degras, petroleum compounds, and herring oil made in the United States and in Japan and Europe, the latter competing with it principally in Europe. For further data in regard to this oil, especially the methods of manufacture, extent of production, and so forth, see pages 255–265.

HERRING OIL.

The herring, including its related species—the sardine, pilchard, sprat, anchovy, etc.—is probably the most valuable and important product of the world's fisheries, not so much on account of the choice nutritive qualities, perhaps, as because of the enormous quantities obtained. When the product exceeds the demands of the food markets, including those required for salting, canning, etc., these fish furnish excellent material for oil-production. Their utilization for this purpose is by no means of recent origin, the production of herring oil in the Bohuslan fisheries of Sweden over a century ago ranging between 1,000,000 and 2,000,000 gallons annually. Nor is it of limited geographical distribution, as the oil is produced to a greater or less extent in nearly every maritime country of Europe, in the British North American provinces, on the northern coast of the United States, in Japan, certain parts of the African coast, etc.

Since only the surplus or waste fish are used in oil-making, and as the catch fluctuates greatly, it follows that much variation occurs from year to year in the quantity produced. The figures showing the output in a certain territory are quite unreliable for any year except the one to which they particularly relate. It is therefore difficult to approximate the product of herring oil throughout the world. It seems probable, however, that a reliable estimate would place the average annual yield at not far from 3,500,000 gallons, of which only a small portion is produced in the United States.

During the fifteen or twenty years preceding 1875, when fish oils

PRIMITIVE FORM OF KETTLE AND PRESS FOR RENDERING OIL FROM HERRING ON THE MAINE COAST.

MODERN TYPE OF HYDRAULIC OIL-PRESS USED IN THE MENHADEN FACTORIES. (SEE P. 262.)

were worth about double their present values, there were small plants all along the eastern coast of Maine for utilizing the herring in oilmanufacture. The crude material consisted principally of refuse fish taken in connection with the smoked-herring business, especially the small fish which otherwise were valueless. Sometimes the larger herring—over 6 inches in length—were utilized, but only when the comparative prices of oil and smoked fish warranted. This business did not engage the attention of large establishments, but was conducted by many fishermen in a small way, each man working for himself.

As the refuse herring accumulated they were sprinkled with salt, using about 1 bushel to 3 or 4 barrels of fish. After remaining in the salt about 24 hours, they were boiled in open kettles and then subjected to pressure in a screw press with capacity for about $1\frac{1}{2}$ barrels. The average yield was about 16 gallons of oil to the ton of fish, but at times the fish were so fat that 20 and even 25 gallons were secured to each ton. The chum or scrap was partly dried and then sold as fertilizer at about \$12 per ton.

The development of the sardine business furnished more profitable use for small herring, and since 1875 the waste from the sardine canneries has provided most of the material for herring-oil production in Maine. This waste consists of the spoiled fish and of the heads and viscera of fish used in canning, each factory generally using its own refuse. The extent of the business is small. The total output in 1889 amounted to 34,316 gallons of oil, valued at \$8,580, and 1,941 tons of scrap, worth \$15,528. Owing to the decreased value of the oil, this business has since fallen off considerably, the output in 1898 amounting to only 12,672 gallons of oil, worth \$2,116, and 785 tons of scrap, worth \$5,910.

The method of manufacture is described by Mr. Ansley Hall on page 479 of Report of U. S. Fish Commission for 1896.

Considerable quantities of oil have been prepared from herring on the Pacific coast of the United States. The industry dates from 1867, but the output was irregular for a number of years. In 1885 the product amounted to upward of 200,000 gallons, much of which is alleged to have been sold as whale oil. In 1892, according to the *Oil*, *Paint, and Drug Reporter*, the output approximated 500,000 gallons, 60 per cent of which was prepared at Killisnoo, Alaska. The yield of oil ranges from 1 to 4 gallons to the barrel of fish. The value on the Pacific coast is about 20 cents per gallon, and the dried scrap sells for about \$25 per ton. This oil is usually quite clear, and the foots extracted in refining are nearly as white as spermaceti and sell for about 1 cent per pound less than tallow from sheep and oxen, being used largely by soap-makers on the coast.

When herring are taken in the fisheries of Europe in such quantities that they can not be profitably used for food, it is customary to convert them into oil and fertilizer. Herring oil is extensively manufactured in Norway and Sweden, and with the exception of that obtained

238 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

from cod livers, it is now the principal fish oil of those countries. The manufacture in Sweden developed rapidly eight or ten years ago, due to the abundance and consequent cheapness of herring. According to Capt. J. W. Collins, the number of factories increased from 3 in 1891 to 22 in 1895, the output in the season of 1895–96 amounting to about 500,000 gallons of oil and 16,000 tons of fertilizer. The scarcity and consequent high price of herring since 1896 have greatly restricted the output of these factories.

In the preparation of sardines in Europe the heads, viscera, and other waste parts are generally utilized in oil-production. They are cooked and pressed, the oil separated, and the refuse used for fertilizer. This oil is employed in leather-dressing, cordage-manufacture, the preparation of paints for exterior surfaces, and, in some country districts, for illumination. Unfortunately, we have no data bearing on the total extent of the output.

The herring-oil industry in Japan is probably much older than its counterpart, the menhaden industry in America, but it was in a crude state up to about twenty years ago. The species of fish utilized—known as "iwashi"—is found in large schools along the Japanese coast, especially on the northern side of the main island, and very large catches are made in the fall and winter, when the fish are fat.

According to a recent report by Consul Van Buren, of Kanawaga, the principal fisheries are on the island of Yezo and the peninsula of Ava, near Yokohama. The method of extraction is similar to that employed in the United States. The fish are cooked and pressed and the residuum used for fertilizer. The process of refining is likewise similar to that employed in America, the oil being pressed " in small filtering bags of paper, outside of which are similar ones of strong cloth. A number of these are placed in a press, which forces out the oil through the pores of this double envelope."

Japanese herring oil contains an unusually large amount of foots, amounting to about 25 per cent, according to some refiners. On account of this, the weather-test of the crude oil is high, from 65° to 70° F. Before the introduction of kerosene in Japan, refined herring oil was employed largely for illumination, but that is greatly reduced. It is now used locally in the manufacture of soap, in leather-dressing, in cordage-manufacture, as a body for paints, and for other technical purposes.

Since 1881 large quantities have been exported to Europe, and also at intervals to the United States. At first it found little acceptance on account of its unpleasant odor, due to the crude method of extraction. Another objection was the form of the packages, consisting of second-hand 5-gallon kerosene cans, which proved a nuisance to users of large quantities. The Hamburg market price is about 40 marks per 100 kilograms for the light oil and $37\frac{1}{2}$ for the brown. The foots, after the process of refining, sell at about 43 marks per 100 kilograms.

It is only when domestic fish-oils are high that Japanese herring oil

AQUATIC PRODUCTS IN ARTS AND INDUSTRIES. 239

can be profitably imported into this country, and on that account the imports fluctuate largely from year to year. The United States markets will receive it at 3 to 5 cents less per gallon than menhaden oil, but it can not be exported to this country with profit when the menhaden market is less than 26 cents per gallon, since the freights, insurance, import duties, brokerage, etc., would leave very little for the exporter. In 1885 the imports into this country amounted to 101,265 gallons, valued at \$24,832; in 1886, 5,010 gallons, valued at \$786; then they were insignificant until 1893, when 191,852 gallons, worth \$30,746, were received. In 1894 the imports were 156,456 gallons, worth \$24,656. Some very choice specimens of refined oil have been received from Japan for exhibition purposes, thus demonstrating what the factories there are capable of producing, but some of the product sent here for consumption could be improved upon.

OIL FROM WASTE FISH.

In addition to menhaden and herring, several species of fishes not suitable or available for food are used in oil-production. The use of sea-robin, skates, and bellows-fish taken with menhaden is noted in the account of the menhaden industry. Of these species, the searobin is the most desirable for this purpose, yielding about 8 gallons of oil to the ton of fish. Skates and bellows-fish yield comparatively little oil, amounting sometimes to less than 1 gallon to the ton. This is combined with the menhaden oil, no noteworthy difference being apparent. These fish are purchased by the menhaden factorymen at 50 to 75 cents per thousand, but it would not pay to handle them were it not for the fertilizer into which the solid tissue is converted after the extraction of the oil. The oil of the sun-fish (*Mola*) is used by some fishermen for the cure of rheumatism.

On the coasts of Alaska and British Columbia, and to a less extent in Washington and Oregon, there is secured a fish closely allied to the smelt and capelin of the Atlantic coast, which is of considerable value owing to its oil-yielding properties. This is the eulachon or oulahon (*Thaleichthys pacificus*), called also the "candle-fish," for the reason that the natives use it as a candle in their dwellings, it being capable of ignition and burning with good illuminating qualities. For many years, according to Dr. Tarleton H. Bean, an excellent quality of oil has been made from it by the Indians both for their own use and for trade with the whites. The weather-test of this oil is very high, and at ordinary temperature it is opaque and butyraceous; indeed, among the Indians it supplies the place of butter.

According to Dr. A. B. Lyons, of Detroit, eulachon oil contains "about 20 per cent of palmitic and stearic acids, 60 per cent of olcic acid, 13 per cent of an unsaponified substance, which is the most peculiar and interesting thing about it. This substance is of an oily consistency at ordinary temperature in summer, has much lower spe-

cific gravity than oleic acid or any other constituent of ordinary fats (specific gravity 0.865 to 0.872 at 59° F.^{*a*}), and seems to resemble the unsaponifiable constituent of sperm oil."^b According to Dr. Schaedler, when eulachon oil is mixed with sulphuric acid (1 volume of acid to 5 parts of oil) the temperature of the mixture rises to 121° F., whereas under similar conditions cod oil rises to 235° F. This acid does not impart to eulachon oil the beautiful purple color that it does to cod oil, but a deep brown, subsequently inclining to reddish yellow. Under saponification the precipitated fatty acids amount to about 95 per cent of the original bulk of the oil. Efforts have been made to introduce eulachon oil in the markets in competition with cod-liver oil for medicinal uses. It is claimed that it has nourishing and stimulating properties that adapt it to certain cases of malnutrition, and that it is more easy of digestion than cod-liver oil.

Large quantities of lamprevs are used for oil-rendering in southern Russia. Prior to 1870 the lamprey was not an article of commerce there, except a small quantity used locally as candles in much the same manner as the eulachon on the Alaskan coast. It is now taken in large numbers on the Volga and Kur rivers. A small quantity is pickled for food, but the greater portion of them are used in oil-manufacture. It is reported that between Tsaritsin and Yenotavevsk, on the Volga River, about 50,000,000 lampreys are taken annually, vielding about 100,000 gallons of oil.^c When properly prepared this oil is clear and transparent, but it contains a large quantity of glue, and consequently it is quite viscous.

OIL FROM FISH HEADS.

During the last twenty years the market has received considerable oil made from refuse at the salmon canneries on the Pacific coast. This was first prepared, about 1876, at a factory above Astoria, on the Columbia River. The heads alone were utilized. These were purchased at the canneries at the nominal price of 50 cents to \$1 per 1,000. that quantity yielding from 30 to 35 gallons of oil.^d The heads were cooked by steam and the oil expressed from the mass. This product was sold for use on the Pacific coast at prices varving from 22 to 35 cents per gallon according to the supply and demand. The output of salmon oil was small until 1895, when somewhat more than 50,000 gallons was received on the market. In 1899, according to Mr. W. A. Wilcox, two small establishments at Astoria for utilizing salmon refuse prepared 19,600 gallons of oil and 140 tons of fertilizer, and one factory at Anacortes, Wash., produced 22,000 gallons of oil and 350 tons of fertilizer. Only a small portion of this refuse on the coast is used. This oil compares favorably with that from menhaden and, being a waste product, can be prepared at a very low price. The vis-

 ^a The specific gravity at 59° F, is given by Dr. Schaedler as 0.907,
 ^b Journ. Soc. Arts, 1884, p. 1107,
 ^c Fishing and Hunting in Russian Waters, p. 27,
 ^d See Fishery Industries of the United States, Sec. V, vol. I, p. 750.

cera of salmon yields such a small quantity of oil that usually it is not profitable to attempt its extraction.

In the United States the heads of halibut have been generally utilized for oil-manufacture since 1870. They are of no value as food and are discarded in dressing the fish for market. In Gloucester and Boston, the headquarters of the halibut fishery, they are collected by the oil-manufacturers, cooked, and pressed in the same manner as other waste products. They are placed in large receptacles and treated with steam until the tissues are thoroughly disintegrated, when the oil and water are extracted by subjecting the mass to hydraulic pressure, 1,000 pounds yielding about 20 gallons of oil. The annual product in Boston and Gloucester is about 12,000 gallons, valued at about 30 cents per gallon. When refined by treating with caustic potash, refrigerated, pressed, and sun-bleached, it looks as fine as choice whale oil and is commonly sold as a substitute therefor and at about the same price.

Sword-fish heads are usually very fat, a single head sometimes yielding one gallon of oil. As a rule, however, 100 heads yield about 65 gallons of oil. It is extracted in precisely the same manner as in case of halibut-head oil. The quantity prepared is small, probably not exceeding 1,000 gallons annually on the entire New England coast. It is clear and sweet and is probably sold as whale or cod oil.

The heads of other food-fish as a rule contain little oil. Cod and related species, for instance, contain practically none, and in utilizing them for fertilizer in this country, as well as in the British provinces and in Norway, no effort whatever is made to secure oil therefrom.

OIL FROM VISCERA OF FISH.

The quantity of viscera resulting from dressing food-fish at the markets, canneries, drying establishments, and the like in the United States amounts to upward of 100,000 tons annually. In certain species of fishes this material is very oleiferous, yielding as high as 150 gallons to the ton; but in most species the viscera are so poor in oil as to preclude their use for this purpose, the possible yield in some instances being as low as 4 or 5 gallons to the ton of crude material.

Probably the greatest yield of oil is from the viscera of the blue-fin white-fish and the chub or deep-water herring of Lake Michigan. The quantity ranges from 7 to 16 gallons of oil to the barrel and is much greater in winter than in summer. The average quantity of oil from the waste of lake trout is about 4 gallons to the barrel of 200 pounds. The yield from herring is small, probably not exceeding 1 gallon per barrel. The total quantity of oil contained in the viscera of all foodfish taken in the United States amounts probably to upward of 800,000 gallons. Only a relatively small proportion of this oil is saved.

Very few establishments exist in this country for utilizing the oil contained in the viscera of fish. A majority of these are on the shores

F. C. 1902-16

of the Great Lakes, especially Lake Michigan, owing to the fatness of the waste from chubs (Hoy's white-fish) secured in great quantities in that lake. These establishments are small, the necessary pots or kettles, boxes, barrels, etc., not exceeding \$300 in value. The viscera are usually saved by the fishermen in tight barrels furnished by the oil men, who receive this refuse for carting it away; water is added, and the whole mass cooked in large open pots or kettles for a length of time ranging from three to six hours. As the oil accumulates at the surface it is skimmed off and stored in suitable receptacles, the solid matter being discarded as of no value. When a barrel or two of oil has accumulated, it is reboiled and coarsely refined.

There are 8 or 10 of these oil-producing plants on the shores of the Great Lakes, and the total output probably does not exceed 20,000 gallons, whereas the total possible is upward of 200,000 gallons. One plant at Sheboygan, Wis., receiving the viscera from a catch of 296,365 pounds of blue-fin white-fish and chubs and of 110,260 pounds of trout in 1899, produced 1,180 gallons of oil, which sold for \$301.

Considerable oil exists in various parts of the body of sturgeon, especially in the viscera and under the dorsal scutes or bosses. In the sturgeon fisheries of Russia it is customary to extract this oil and use it not only technically but also for culinary purposes and for food, especially to soften caviar when it is somewhat dry. A few hundred gallons of sturgeon oil are prepared in the United States each year, but no special properties are attributed to it. It sells for about the same price as menhaden oil and is used for similar purposes. As a general rule, owing to its preparation from fresh materials, this oil is clear and bright and of pleasant odor and flavor.

MISCELLANEOUS OILS.

Alligator oil is much used among the hunters and swampers of the Gulf States. It is employed as a lubricant, an illuminant, for softening leather, and in the treatment of rheumatism, scrofula, etc. Although this oil is rarely met with in commerce, there are probably few professional alligator hunters who do not lay in a supply each season. About fifteen years ago alligator oil was introduced in France for leathercurrying and met with much favor, owing to its imparting greater weight to the leather than whale, seal, or cod oils. It was received from Mexico and Central America and sold in France at about one france per kilogram, equivalent to about 70 cents per gallon. It is described as of a reddish color, of 0.928 specific gravity, and to consist chiefly of 60 per cent of olein, 32 per cent of margarine and stearin, $1\frac{1}{2}$ per cent of free oleic acid, and 0.02 of iodine.^a

In many parts of the world oil is extracted from various species of turtle or terrapin and used for medicinal or technical purposes. In the Chesapeake region certain remedial qualities are supposed to exist in the oil of the celebrated diamond-back terrapin. It has been recommended especially for rheumatism. But little of this oil finds its way into trade, being for the most part bottled and put away in the family medicine-chest for home use only. The oil from a variety of turtle found in Mauritius and the adjacent islands has had a local reputation for more than two centuries as an excellent remedy in several diseases. On the coast of India turtle oil is prepared for a number of purposes, especially in the composition of a cement or pitch for paying the seams of vessels. It has been highly recommended as a medicinal oil, principally in cases of scrofula and anæmia. It is not often refined, notwithstanding that the percentage of foots is large. When bottled, the solid part is precipitated in an opaque and yellowishwhite mass, leaving the oil transparent and brownish in color. When slightly warmed, as by exposure to the sun's rays, the two parts amalgamate.

Considerable quantities of turtle oil are prepared in the West Indies, on the northern coast of South America, on the Seychelles in the Indian Ocean, etc. Not only is the fat of the animal used for this purpose, but likewise the eggs, of which large numbers are secured on the Amazon and the Orinoco. It is said that a single turtle may yield 6 gallons of oil, and that 3,000 eggs are required for an equal quantity. The eggs are crushed, covered with water, and submitted to the heat of the sun, whereupon the oil quickly floats to the surface. According to consular reports, Para receives upward of 50,000 gallons of this oil during some seasons, and a much larger quantity is consumed by the natives inhabiting the shores frequented by the animals.

Turtle oil is used for culinary purposes, and likewise for illumination, lubrication, and currying.

While the oils of the dugong and of the manatee are comparatively unknown in the United States, they are of considerable local importance in several tropical and semitropical countries, especially in Australia, New Zealand, and Brazil. The oil is obtained from the blubber situated beneath the skin, and each animal yields 5 to 20 gallons. No difference has been pointed out in the characteristics of the oils of these animals; although, obtained in widely separated countries, it is natural that different uses should have developed.

Dugong oil has no prominent odor, is of a pleasant flavor, and when in good condition is almost as limpid as water. It is used in place of butter and sometimes in preference thereto, and as a cooking oil it is said to be unrivaled; but it is employed principally as a medicine, its properties resembling those of cod-liver oil, without the unpleasant effects of the latter. It is valued by some medical practitioners in Australia and New Zealand even more highly than cod-liver oil. Dr. Hobbs, of Queensland, was the first to draw attention to its virtues in Australia, receiving a prize medal at the Sidney Exhibition in 1854. By some persons dugong oil is believed to be efficacious in the treatment of debility, dyspepsia, chronic dysentery, bronchitis, etc. Occasionally it may be found in this country put up in bottles with labels

• indicative of an oriental origin, and recommended as a cure for consumption and diseases of the chest and back.

The oil of the manatee is one of the few blubber oils which does not become rancid on exposure to the sun, and on the contrary acquires a fine flavor and agreeable odor through such exposure. On the west coast of Africa, in the West Indies, Guiana, and Brazil, it forms an important item of domestic commerce; it is used as a lubricator, as an illuminant, in cooking, and for the table.

Speaking of the American species (*Manatus americanus*), Dr. R. Brookes in his "Natural History" states:

The fat which lies between the cuticle and the skin, when exposed to the sun, has a fine smell and taste, and far exceeds the fat of any sea animal. It has this peculiar property, that the heat of the sun will not spoil it, nor make it grow rancid. The taste is like the oil of sweet almonds, and it will serve very well in all cases instead of butter. Any quantity may be taken inwardly with safety, for it has no other effect than keeping the body open. The fat of the tail is of a harder consistence, and when boiled is more delicate than the other.

The fat obtained from beaver is made into an ointment by the Indians, to which they attribute many curative and medicinal properties, especially its power to prevent frost bites, the anointed parts of the body not being affected even when exposed to the most extreme cold. An old treatise of 1685, credited to Joanne Mario, attributes marvelous curative properties to beaver oil:

It is efficacious in all maladies which affect the nerves. It is useful in epilepsy, and prevents apoplexy and lethargy; stops spasms and convulsions, and is of great help in giddiness, toothache, asthma, dysentery, and strains.

On the Macquarie Islands, the coast of Patagonia, and several other places in the cold regions of the Southern Hemisphere, large numbers of penguin are caught and used in oil rendering. On Macquarie Island the royal penguin and the king penguin are used, while on the Patagonian coast the jackass penguin is the principal species, with smaller numbers of macaronis and red bills. These birds are found on the shores in great numbers and are easily killed with clubs. In some localities the breast skin, with the attached blubber, is the only part cooked, the rest being discarded; but usually the entire body is placed in pots and cooked. When thoroughly disintegrated the mass is pressed and the oil thus extracted.

SPERMACETI REFINING AND MANUFACTURE.

Spermaceti is the solid portion of the crude oil of sperm whales and of certain other cetaceans. As noted in the chapter on sperm-oil rendering, it occurs in a state of solution in special cavities of the skull and to a much less extent in various parts of the body, especially in the core of the dorsal hump. The process of its extraction and the separation of the oil therefrom have already been noted in the account of rendering sperm oil, and it now remains to describe the subsequent treatment of the crude and refined spermaceti. After the extraction of the "taut-pressed-oil" the crude spermaceti is heated in vats or tanks, refined, and "whitened" by the introduction of some alkali, as a weak solution of caustic soda or caustic potash, to saponify any adhering oil. Care must be taken during this process that the spermaceti does not saponify, any tendency to do so being overcome by the addition of brine. The refined product is then molded into suitable shapes for marketing. Most of it is formed into blocks measuring 10 by 12 by 14 inches, and weighing about 62 pounds each. It is also molded into cakes weighing 1 pound, halfpound, quarter-pound, or of any other desired weight.

Spermaceti is white, semitransparent, unctuous or talcose to the touch, of a slight fatty taste and odor. A fracture of a cake reveals broadly foliated, crystallized pieces resembling quartz. According to Brannt, its specific gravity is 0.943 at 59° F. It yields nothing to water, and very little to cold alcohol, but is readily soluble in ether, chloroform, and bisulphide of carbon. It melts at about 125° F. and congeals immediately below the melting point. Its component parts, according to the same chemist, are carbon, 80.03 per cent; hydrogen, 13.25 per cent, and oxygen, 6.72 per cent.

It is not easy to adulterate spermaceti without detection, since its characteristic properties are readily diminished, the compound being harder, with decreased nacreous luster and smaller foliated crystals. Tallow is readily detected by the odor given off in melting, and also by the compound making fat stains on paper, which is not the case with pure spermaceti. Stearin renders it harder and smaller foliated, and its presence is readily detected by boiling the sample in a soda solution, effervescence occurring in the adulterated article. If exposed to the air for a long time spermaceti becomes yellowish and somewhat rancid, but when remelted and treated with diluted caustic soda or potash it regains its original condition.

In the early history of the sperm-whale fishery spermaceti was considered of great value for medicinal purposes, and was recommended for many ills of the body, but was employed principally for internal applications, especially in cases of inflammation. It was so much in demand before the full development of the fishery as to sell at times for its weight in silver. As it became better known, however, it occupied a minor position in materia medica, chiefly in the preparation of ointments, and its principal use was in candle-making.

The beginning of candle-making in America dated from about 1750. The number of factories increased rapidly, and in 1761 there was a total of eight in New England and one in Philadelphia. In 1772 the first candle factory was established at Nantucket, then the headquarters of the whale fishery, and the number increased until there were 10 in existence on the island in 1792, and an equal number then existed at New Bedford.^{*a*} The business of preparing spermaceti was then separate from the general whale-oil refining industry, the candle-

a New Bedford Medley, Nov. 30, 1792.

makers purchasing the crude head matter only. But gradually the two industries were combined to their mutual advantage. When the sperm-whale fishery developed to its full capacity, the production of spermaceti was very large, averaging more than 3,000,000 pounds annually from 1835 to 1845. With the decrease in extent of the fishery, there was a corresponding decrease in the yield of spermaceti, reaching its lowest product in 1890, when less than 200,000 pounds were prepared.

Spermaceti is among the very best materials for candle-making, the product being beautifully semitransparent and nacreous, burning with great regularity and with white light of high illuminating power; vet owing to the cheapness of other materials, especially paraffin, only a small percentage of the candles used at present are made of this material. To reduce the tendency of spermaceti to crystallize in molding and consequently lower its friability, it is customary to add a little paraffin wax, tallow, stearin, beeswax, or cerasin. The clear natural color of the refined spermaceti is usually preferred in candles. but sometimes coloring material is introduced, in so small a quantity, however, as not to destroy the transparency of the spermaceti. Α yellow tint is imparted by adding gamboge, a red by carmine, and a blue by prussian blue. Owing to the cheapness and excellence of paraffin candles, the consumption of spermaceti in candle-making has been greatly reduced. The quantity thus used at the present time bears no relation to the extensive use of petroleum wax for that purpose, the consumption of which in Great Britain alone amounts to upward of 50,000 tons annually.

Sperm candles are at present the standard used by the principal gas-examiners for photometric measurements. The rules for the preparation of standard sperm candles for photometric purposes, published by the Metropolitan Gas Referees, of London, prescribe that, for the purpose of rendering the spermaceti less brittle, best airbleached becswax, melting at about 144° F., shall be used exclusively, and that the proportion of beeswax to spermaceti shall not be less than 3 per cent nor more than $4\frac{1}{3}$ per cent; the spermaceti itself to be so refined as to have a melting-point lying between 112° and 115° F.^{*a*}

The production of spermaceti in 1901 in the United States was about 400,000 pounds, worth \$100,000. Of this amount probably 70 per cent was exported to Germany, England, and other foreign countries. Its principal foreign use is in the making of candles, large quantities being made in England and Germany for ecclesiastical use, especially in southern Europe. Minor uses are as an ointment for medicinal purposes, in laundries for producing a polish on linen, and for self-lubricating cartridges. Of the domestic consumption, probably 5,000 pounds are used in candle-making and the rest for medicinal and industrial purposes.

a Journal Society Chemical Industry, 1894, p. 65.

SPERMACETI REFINING. VAT FOR BOILING AND REMOVING SEDIMENT.

PACKAGES OF BLOCKS, CAKES, AND CANDLES OF SPERMACETI.

During the year 1901 the value of spermaceti greatly decreased, sales during November being made at 22 cents per pound, the lowest price reached in the last ten years.

No exact figures are available to show the product of spermaceti during a period of years, but the approximate yield may be determined from the figures on page 204, showing the yield of sperm oil, remembering that about 25 pounds of spermaceti is obtained from a barrel, or 31½ gallons, of sperm oil. It should be noted, however, that considerable crude sperm oil is exported and the spermaceti extracted abroad.

AMBERGRIS.

Ambergris is a wax-like substance found at rare intervals, but sometimes in relatively large quantities, in the intestines of the sperm whale. With the exception of choice pearls and coral, it is the highest-priced product of the fisheries, selling at upward of \$40 per ounce. It has been a valuable object of commerce for hundreds of years. It appears to have been prized first by the Arabians, by whom it was called amber, and by this name it was first known among the Europeans. The name was later extended to the fossilized gum, the two being distinguished by their respective colors as amber gris and amber jaune.

In the writings of early travelers to the shores of the Indian Ocean and to southern Asia, references to ambergris are by no means infrequent. Before the time of Marco Polo (1254–1324), Zanzibar was famous for its ambergris. So plentiful was it on the shores of Indian Ocean in the sixteenth and seventeenth centuries that the name was given to various islands, capes, and mountain peaks of that region. It was also found on certain shores of the Pacific, notably the coast of Japan. From their station in Batavia the Dutch traders kept Europe supplied, and also exported it to Asiatic markets.

Though ambergris was a valuable commercial article, little or nothing was known of its origin before the eighteenth century. Some supposed it to be the "solidified foam of the sea," others that it exuded from trees and flowed into the sea, or that it was a "fungoidal growth of the ocean analogous to that on trees."

It is now generally conceded that ambergris is generated in either sex of the sperm whale, but far more frequently in the male, and is the result of a diseased state of the animal, caused possibly by a biliary irritation, as the individuals from which it is secured are almost invariably of a sickly appearance and sometimes greatly emaciated. It is not of frequent occurrence, many whalemen with half a century's experience never having seen any. The victim of the malady may eject the morbific substance, thus furnishing the lumps which have been found on the shores or floating on the seas frequented by sperm whales.

Although ambergris is of such rare occurrence, the sperm-whalers always search for it, especially in diseased or emaciated whales. It

is found in all parts of the intestinal canal, but more generally at 2 to 6 feet from the vent. The instrument used in the search is a common cutting-spade. The presence of the prize is detected by the peculiar feeling or impression on striking it, very much like the cutting of cork or rubber, and also by its sticking or adhering to the spade, or by its floating out upon the water when the intestines are opened.

Ambergris occurs in rough lumps varying in weight from less than 1 pound to 150 pounds or more. It generally contains fragments of the beak or mandible of squid or cuttle-fish, which constitutes the principal food of the sperm whale. When first removed from the animal it is comparatively soft and emits a repugnant odor, but upon exposure to the air it grows harder, lighter in color, and assumes the appearance it presents when found floating on the ocean. It is light in weight, opaque, wax-like, and inflammable. Its color ranges from black to whitish gray, and is often variegated with light stripes and spots resembling marble somewhat. When dried—the only curing process it undergoes-it yields a subtle odor faintly resembling that of honey. It softens under heat like wax, and in that condition may be easily penetrated by a needle. A proof of its good quality is a polished needle meeting with no obstacle when thrust through it, and if the needle be red hot the substance will exude an oil. It fuses at 140° to 150° F., and when heated to 212° F. it dissolves into a blackish, thick oil, and gradually evaporates, leaving no trace of its presence. When stored for a length of time it becomes covered with dust like It contains some moisture that gradually evaporates, chocolate. reducing its weight, but increasing its intrinsic value.

The amount of ambergris produced annually from all sources varies greatly, scarcely an ounce being obtained in some years, while in others the product may exceed \$50,000 in value. The small compass within which a very valuable quantity may be stored without attracting attention, and the ease with which it may be brought in where it is deemed advisable to preserve secrecy concerning a find, render it exceedingly difficult to follow closely the imports of the article. However, a brief account is here given of some of the principal masses obtained. In this compilation we are indebted to Mr. Francis II. Sloan and to Messrs. J. and W. R. Wing for information.

Probably the most valuable piece secured previous to the last century was a 182-pound lump purchased in 1693 from the King of Tydore by the Dutch East India Company for the sum of 11,000 thalers. Its origin is unknown. Probably it was found afloat on the sea or drifted ashore. It is stated that the Grand Duke of Tuscany offered 50,000 crowns for it—with what success is unknown.

An American fisherman is credited with finding a piece that weighed 130 pounds in a whale secured in 1782 about 150 miles southwest of Windward Islands. This sold for £500, the low price leading one to fancy that the reported weight is exaggerated.

Captain Coffin, a British whaling master, stated before a committee of the House of Commons in 1791 that—

He had lately brought home 362 ounces, troy, of this valuable substance. He had taken this from the anus of a female sperm whale captured off the coast of Guinea, and which he stated was very bony and sickly. At the time he brought this quantity to England the ambergris was selling for 25s. an ounce, but he stated that he sold his for 19s. 6d. per ounce to a broker, who exported it to Turkey, Germany, and France, among the natives of which it appears to have been long celebrated for its aphrodisiacal properties.^a

The schooner *Watchman*, of Nantucket, is credited with bringing home from the Bahama Islands, in 1858, the largest mass ever found, weighing nearly 600 pounds. This was on the market for many months, as the owners were unwilling to divide it and dealers were adverse to taking the whole lot, but finally it was sold for \$10,500.

The bark Sea For, of New Bedford, in 1866, secured a 30-barrel sperm whale off the eastern coast of Arabia. A long-handled cutting spade was thrust into the region of the anus and a piece of ambergris fell out. Some of the men proceeded to cut open the large intestine, which was about 10 feet long and $3\frac{1}{2}$ inches in diameter, and for the entire length it was literally filled and closely packed with ambergris. They cleand out the stomach and found two large pieces weighing, respectively, 40 and 41 pounds. The ambergris in the large intestine, to all appearance, was originally composed of globular pieces, which, owing to pressure from all sides, were compressed into irregular shapes. The two large pieces found in the stomach were of a different shape from those found in the intestine. They measured about 36 inches in circumference, were flat on both sides, about 8 inches in thickness, and of a superior quality. The entire mass weighed 150 pounds and was sold to the Arabs of Zanzibar for \$10,000 in gold.

During the year 1878 the bark *Minnesota*, in the same locality, found 18 pounds of ambergris in a whale, which was sold in Zanzibar to the agents of the Sultan for \$150 per pound.

The bark Adeline Gibbs in 1878 brought in the most valuable lot of ambergris obtained by an American vessel up to that time. It was taken from a 50-barrel bull sperm whale south of St. Helena, weighed $132\frac{2}{4}$ pounds, and was sold for \$23,231. This piece was the only one that a fleet of 12 vessels had taken in 45 years. About the same time the *Bartholomew Gosnold* secured 125 pounds in the vicinity of New Holland, which sold for about \$20,000, and the *Lettitia* brought in 100 pounds, worth \$17,500.

In 1882, the bark Falcon, in latitude 16° 55′ S. and longitude 11° 00′ W., secured a 28-barrel male sperm whale, which was apparently in healthy condition and without unusual appearance. A spade was accidently thrust into the abdomen, revealing the presence of ambergris in the viscera. A large piece of an ovate form, weighing about

60 pounds, and several smaller pieces, irregularly shaped, were found in the intestinal canal. Some of the ambergris was brownish black on the outside and some of a grayish yellow cast; the exterior coating was filled with the mandibles of squid. The gross weight was 136 pounds, and it sold for \$14,000.

Doubtless the most valuable lot ever secured was a mass weighing 162 pounds 11 ounces, obtained in 1891, known as the "Bank" lot, which sold in London for about £10,000. The following communication from the brokers who effected the sale of this remarkable find furnishes an excellent description of the lump and of the state of the ambergris market:

About the end of August, 1891, a gentleman called to consult us as to the best means of disposing of some ambergris which had been consigned to his firm. We suggested that if it were brought to us we could examine it and report upon its value, but when we were informed that the case which contained it weighed close on 224 pounds and was too large to go inside a cab our first feeling was one of incredulity as to the consignment being ambergris at all. It was finally decided that the case should remain in the strong room of the bank in which it had been deposited for safe custody and that we should go there to inspect it. This we did, and were shown a box measuring about 2 feet 4 inches in each direction and which we were told had with its contents been insured for £10,000.

In the presence of the merchant who had consulted us and the bank officials the lid of the case was opened, with the immediate result that everyone beat a hasty retreat from its vicinity, for the horrible smell which issued from the box was overpowering. When the odor had lost somewhat of its intensity, we began to take out the packing and found that the case (which was tin-lined) contained one huge mass of a blackish substance, measuring 6 feet 4 inches in circumference, nearly spherical, and which was undoubtedly ambergris. On being turned out of the case it was found to be saturated with moisture, as were the packings of paper and old gunny which had been put around it to prevent it from chafing to pieces during the voyage; and it was the liberation of the gases generated by the salt water and the animal matter which had caused the stench alluded to. By proper treatment this smell was eventually completely got rid of, and the ambergris obtained in marketable condition. The mass was next weighed and the certificate signed by the interested parties, the exact weight being at that time 2,603 ounces. or 162 pounds 11 ounces. This is probably the largest piece of ambergris which has ever been seen by anyone living, and approaches nearly in weight to the lump of 182 pounds purchased by the Dutch East India Company two hundred years ago.

The next thing to do was to split the lump, so as to see what the interior was like. This was accomplished with the aid of long chisels and crowbars. We then saw that the substance consisted of layers or lamina rolled around a central core, the lamina varying a good deal in texture, color, and flavor. Speaking generally, the outer layers were thin, friable, and shelly; dark, almost black in color, and mixed to a considerable extent with the beaks of the cuttle-fish, on which the whale feeds. As the layers approached the center they were denser, grayer in color, thicker, and of better flavor, until the core itself was reached. This core really consisted of two pieces, one the shape of a rifle bullet, but with a deepish depression like the "kickup" of a wine bottle in the base. It was from 10 to 11 inches high, with a diameter of about 6 inches at the bottom, tapering upward to about 2 inches at the top, which was slightly flattened. It was detached from the surrounding layers with the gratest ease, and stood alone, a pure, solid lump of the finest gray ambergris, weighing 834 ounces. Beside this magnificent piece was a smaller one, almost spherical in shape and about the size of a very large orange. It was rather darker in color and not of quite so fine a flavor, but was as easily detached from the surrounding layers as the other. Neither of these pieces contained any of the beaks which were so common in the outer layers, and it is almost needless to say that they realized by far the highest price which was obtained for any portion of the mass. The layers nearest to the core were of much finer flavor than the outer and darker. One of them was quite 4 inches in thickness, and the ambergris of which it consisted was of a silvery-gray color, different from the whitish gray of the core, and was of lower specific gravity. The layer outside this again was striated in places with the darker exterior, and the beaks began to show, though not to the same extent as in the black, shelly, exterior layers.

It is a matter of some regret to us that we did not secure a photograph of this extraordinary lump, but the fact weighed heavily upon us that if the real truth about it leaked out the depression of the market would be so great that we should not be able to do justice to our clients, and, consequently, as few people as possible were let into the secret. It is true that reports about it were rife for a month or two, but as nothing authentic could be ascertained they gradually died out, and we have ourselves been repeatedly assured that the thing was a myth altogether, one gentleman going so far as to tell one of our partners, about three months afterwards, that he held three-fourths of the total quantity of ambergris in London, not knowing that we were controlling about 1¹/₂ hundredweight.

Probably the finest lot of ambergris received in America was taken in 1894 by the schooner *Adelia Chase* from a 50-barrel whale near Cape de Verde Islands. It weighed $109\frac{5}{8}$ pounds and sold for about \$26,000, the best parts fetching \$350 per pound. No large finds have been reported since 1894. In 1899 50 pounds of poor quality was secured by the bark *Charles W. Morgan* off the coast of Japan. In 1900 the *Morning Star* secured 7 pounds, and in 1901 the same ship brought in 20 pounds of medium quality.

Ambergris has been used for centuries in the sacerdotal rites of the church, and, in connection with fragrant gums, it was formerly burnt in the apartments of royalty. It was formerly used in cookery, especially in the East, being added to flavor certain dishes. This custom spread through western Europe to a limited extent. Macaulay refers to rumors in connection with the death of Charles II of England that "something had been put into his broth, something added to his favorite dish of egg and ambergris." The principal use of ambergris, however, was as a medicine and as a perfume, especially in Asia and Africa. Until recently it held a place in pharmacy, being regarded as a cardiac and antispasmodic, somewhat analogous to musk, and was recommended in typhoid fevers and various nervous diseases.

The principal and almost the only use of ambergris at present is in the preparation of fine perfumes, furnishing an important ingredient in the production of choice bouquet of "extracts." It also acts as a "fixer" and serves to impart homogeneity and permanency to the different ingredients employed. For perfumers' use it is generally made into an essence or tincture by dissolving 4 ounces in a gallon of alcohol. This is facilitated by first crushing and mixing it with sand.

Perfumers exercise much care in the selection of the ambergris which they use. The wholesale dealer grades his stock of the material according to its odor, appearance, etc. But this is by no means sufficient for the trained olfactory sense of the perfume-manufacturer. Before determining the use of a special lot he tests it by his own standards, and these tests may extend over a month, especially for durability of perfume. Some manufacturers prize most highly those lots and grades which another manufacturer would not accept. The selection of just the proper quality to produce the desired bouquet forms one of the niceties of the perfumer's art.

The value of ambergris depends largely on its scarcity at the time and its freedom from impurities. During the last thirty years it has varied in price from \$5 to \$40 per ounce. At the present time it is quoted at \$8 to \$30 per ounce. In 1880 crude ambergris brought home by the whalers was sold at \$10 an ounce and the dried article at \$20 an ounce. In 1876 the value, dried, was \$25 an ounce. In the London *Price Current of Colonial Produce* in 1807 ambergris is quoted at 40s. to 45s. per ounce for "gray, fine." Considering the respective purchasing powers of money two centuries ago and at the present time, that price is quite equal to the average value in recent years.

AQUATIC PRODUCTS AS FERTILIZERS.

GENERAL REVIEW.

A fertilizer is any substance added to the soil for the purpose of producing a better growth of crops. The food required by plants is supplied in part from the atmosphere, but principally from the soil. If the supply of any one of the necessary ingredients be deficient, a small crop is the result; and the purpose of fertilizers is to supply the plant-foods lacking in the soil.

The general use of fertilizers is of comparatively recent origin, yet the preparation of these substances supports an extensive industry, employing a large amount of capital and many thousands of men. Compared with the immense quantities of barnyard materials, phosphate rocks, etc., the use of aquatic products for fertilizer is relatively small, yet it is by no means unimportant in the fishery industries.

Fish, seaweeds, shells of mollusks and crustaceans, and various other aquatic products have long been known to possess rich fertilizing properties. All kinds of fish can be used for this purpose; but, owing to the greater value of choice species as food, only the nonedible ones and the waste parts are utilized. The menhaden is the only fish taken in great quantities in this country especially for conversion into fertilizer. The output of this species is very large, amounting to 30 per cent of the total catch of fish in the United States, and its capture maintains one of the most extensive and vigorously prosecuted of the American fisheries. Compared with that from menhaden, the quantity of fertilizer made from other fish is small, and only such are used for this purpose as can not be profitably employed in any other way.

The original use of fish for fertilizing purposes was in a fresh or green state, and they were added to the soil directly after their capture, although, of course, no special effort was made to preserve their freshness. Before the advent of the colonists in America, the Indians were accustomed to manure their small crops of corn by placing one or more fish in each hill or by spreading them broadcast over the field, and this practice was followed by the early settlers. Owing to the original richness of the soil and the limited agricultural operations, the use of fertilizers was of comparatively small extent until the latter part of the eighteenth century. It appears that fish were then employed for this purpose all along the Atlantic seaboard from Maine to North Carolina wherever they were obtainable in sufficient quantities.

Fresh fish contain usually from 65 to 80 per cent of water and from 1 to 16 per cent of oil. Neither of these has any value as a fertilizer. On the contrary they decrease the portability and storage qualities of the constituents, and the presence of the oil is prejudicial to the decomposition of the fertilizer when applied to the soil.

Early in the nineteenth century the februmen occasionally extracted the oil from the fish when the laster were unusually fat, thus removing an injurious ingredient, for which valuable uses were found. This resulted gradually in the establishment of factories for removing the oil, and likewise most of the water, so that the fertilizing substance might be in better condition for transportation. At present most of the fish used for fertilizer are treated in this manner, even the farmer-fishermen finding it more profitable to sell their catch at the factories and purchase the scrap; but large quantities of fish in a fresh state are yet used precisely as was the custom three hundred years ago.

Owing to its great abundance, combined with its nonedible qualities, the menhaden is the principal fish used for fertilizer in this country, and the quantity used annually is about 800,000,000 in number, or 240,000 tons round or live weight. Of these fully 99 per cent are handled at the factories, and the remainder are used in a fresh or green state. With the menhaden are taken some skates, sea-robins, bellows-fish, and other waste fish. Aside from a few that may be taken with the menhaden, and occasionally some river herring or alewives, no other fish are captured in the United States especially for fertilizer to any great extent.

Formerly nearly all the waste produced in dressing lish for market was thrown away as useless; but in recent years, in the fisheries as in other industries, the utilization of waste material has been made a subject of careful investigation, and many substances formerly considered refuse are now found to contain elements of commercial value. The dressings at the fish markets and at the fishing centers, the refuse of canneries and boneless-fish factories, and even the carcasses of whales are turned to account in the production of fertilizer. In addition to these materials, the farmers use large quantities of seaweeds, horseshoe crabs, oyster shells, clam shells, etc.

The total annual product of menhaden fertilizer in the United States according to the latest returns amounted to 85,830 tons, for which the producers received \$1,539,\$10. It is difficult to approximate the quantity of other fishery products used for fertilizer, but it is estimated that the waste fish of all kinds amount to about 20,000 tons, worth \$200,000; horseshoe crabs, shells of shrimp, etc., \$00 tons, worth

AQUATIC PRODUCTS AS FERTILIZERS.

\$16,000: shells and agricultural lime, 60,000 tons, worth \$150,000, and seaweeds, 250,000 tons, worth \$312,500, making a total estimated output for this country per year of 416,630 tons, worth \$2,118,310.

THE MENHADEN INDUSTRY.

The menhaden belongs to the *Clupeid* α or herring family, and is about the size of the common herring of the New England coast, but somewhat deeper and more robust. It is not considered a food-fish and is rarely eaten, owing to the abundance of bones, although the flavor is not unpleasant. However, it is one of the most important of all of the species on the coast, being the principal source of bait during the summer, in addition to its use in the manufacture of oil and fertilizer.

The menhaden occurs all along the Atlantic coast of the United States from Maine to Texas, and most abundantly between Cape Cod and Cape Henry, except that during certain years it seeks the coast of Maine in enormous quantities. It appears on the approach of warm weather, ranging from March and April in Chesapeake Bay to May and June on the Maine coast, and remains until late in autumn. Its bathymetrical range extends from the inland limits of salt water to the Gulf Stream, but probably 95 per cent of the catch is made within 2 miles of the coastal line. It is captured principally by means of purse seines, operated from steam vessels with carrying capacity for several hundred thousand fish.

About a guarter of a century ago several important reports relative to the menhaden were issued. The first was that of Messrs. Boardman and Atkins, made to the Maine board of agriculture in 1875.^a Three years later was issued the report of Mr. Luther Maddox.^b Each of these related especially to conditions existing in the State of Maine.

In 1879 the United States Fish Commission published the important report of Dr. G. Brown Goode, containing voluminous notes on the natural and economic history of the menhaden, with many extracts from previous reports on the subject.^c

Many changes have been made in the methods of utilizing the menhaden since those papers were written, but they are yet the principal authorities in regard to the natural history of the subject, and the present writer is prepared to add little. Indeed, such additional matter would scarcely be in place in this paper, which is restricted to the economic use of menhaden in the preparation of oil and fertilizer.

HISTORY AND EXTENT OF THE INDUSTRY.

A century and more ago, when a much larger number of the home requisites were prepared by consumers than is the case at the present time, it was a part of the duties of many farmers along the Middle Atlantic coast to devote a few weeks each spring to taking menhaden for the purpose of fertilizing the cultivated land. Large shore seines made of cotton twine were employed, and in some localities these were owned jointly by several farmers of the vicinity. The length of some of these seines was 3,000 feet or more, and frequently the catch at a single haul numbered several hundred thousand fish, although the average quantity was nearer 10,000 or 12,000. This farmer-fishery has continued up to the present time, but its extent is now very much reduced, owing to the ease with which prepared fertilizers may be purchased.

Following upon the development of this use of fresh or green menhaden came the discovery that the oil was valuable for painting, leather-dressing, etc. Some of the farmers would provide a few casks or hogsheads which they partly filled with fish, adding water to cover them, and with weighted boards placed on top to keep the mass down. On the disintegration of the fish through putrefaction they were occasionally stirred with a long pole to break up the mass and liberate the oil, which floated to the surface of the water and was skinmed off from time to time. After several weeks the oil ceased to flow, and the residuary mass was used as fertilizer. For many years the extent of this business was very small and the product was entirely for home use.

The first improvement in the above process consisted in boiling the fish in kettles to facilitate the extraction of the oil, the boiled fish being then placed in casks, as above noted, resulting in a much larger product. By 1830 the cooking of the fish was quite general among the few persons engaged in extracting oil from menhaden. The oil was dark and erude, and used only for rough painting and leatherdressing, the market being restricted to the neighbors of the manufacturers. The use of kettles, however, involved a great waste of heat, and the business was of very little consequence until the introduction of steam in cooking the fish. The first steam factory, according to the late Capt. E. T. Deblois, was a small one built in 1841 near Portsmouth, R. I.

In 1850 Daniel Wells built a factory on Shelter Island, New York. That was the first factory of considerable size on the coast, and the quantity of fish handled amounted to 2,000,000 or 3,000,000 in number annually. In 1853 Mr. Wells built a new factory on Shelter Island, and the old one was removed to Groton, Conn., being the first steam factory in that State. The first factory in Maine was put up in 1863 at South Bristol, and in 1866 eleven factories were built in Maine. In 1869 the factory at South Bristol, Me., was removed to Fairport, Va., and was the first factory in that State. In the meantime the purse-seine had been improved and adopted in the menhaden fishery, permitting the capture of fish in much larger quantities, and without which the menhaden industry could never have reached its present proportions. The next improvement consisted in pressing the scrap to extract a greater percentage of the oil. The first press, operated by hand power, was built by Charles Tuthill at the Wells factory, on Shelter Island, in 1856. This worked so satisfactorily that soon all the factories were pressing the scrap, and in 1858 hydraulic presses were introduced for the purpose. The high price of oil during the sixtics, when it reached \$1.40 per gallon, resulted in much profit in the business and a large increase in the number of factories, their location extending from Maine to Virginia. Then came the preparation of the scrap in the form of portable fertilizer, the adoption of large cooking-tanks instead of kettles, and the introduction of steam vessels in the fishery.

In 1876 floating factories were introduced. These consisted of boilers, cooking-tanks, presses, etc., mounted on steamers, sail vessels, or scows, for convenience in going from place to place to follow the movements of the fish. Probably half a dozen of these were in use in 1880; but owing to the lack of convenience for drying and handling the scrap, this form of factory was soon abandoned. Another disadvantage of a floating factory is that the constant movement of the vessel prevents the oil from settling, and it remains cloudy and fails to fetch the best market price.

The business continued to expand until it reached high-water mark in 1884, when 858,592,691 fish were caught, yielding 3,722,927 gallons of oil and 68,863 tons of scrap, valued at \$2,800,000. Since that time great improvements have been made in the methods of the industry, but owing to the low price of oil and scrap, resulting from competition with other products, the profits have not been so great, and many factories have been dismantled. The largest catch of fish in any one year, according to figures of the U. S. Menhaden Oil and Guano Association, was 858,592,691, taken in 1884; the smallest was 223,623,750, secured in 1892, and the average catch during the last thirty years approximates 500,000,000 annually. The incomplete returns for 1902 indicate that the catch exceeded 900,000,000, a greater quantity than for any previous year.

There are two separate and distinct sets of figures showing the extent of the menhaden industry during recent years. The first comprises the returns made by the U. S. Menhaden Oil and Guano Association, organized in 1873, and covers the operations of the factories in the United States during each year from 1873 to 1898, inclusive. The second series represents the returns made by the agents of the United States Fish Commission for certain years from 1880 to 1902. Slight differences exist in these figures, but in the main they agree closely.

F. C. 1902-17

The following summary shows the returns made by the United States Menhaden Oil and Guano Association:

Statement of the extent of the menhaden industry of the United States in each year from 1873 to 1898, inclusive, according to the returns of the United States Menhaden Oil and Guano Association.

| Year. | Facto- ries. | Men em- ployed. | Vessels em- ployed. | | a | Fish re- | | Scrap made. | |
|-------|-----------------|-----------------------|------------------------|-------|------------------------|----------------|-------------|-------------|------------------------------|
| | | | Steam- ers. | Sail. | Capital in- vested. | ceived. | Oil made. | Dried. | Crude or acid- ulated. |
| | No. | No. | | | | No. | Gallons. | Tons. | Tons. |
| 1873 | 62 | 2,306 | 20 | 300 | \$2,388,000 | 397,700,000 | 2,214,800 | | 36,299 |
| 1874. | 64 | 2,438 | 25 | 283 | 2,500,000 | 492,878,000 | 3, 372, 847 | | 50,976 |

| 1886. | 26 | 1,154 | -45 | 74 | 1,234,000 | -283, 106, 000 | 1,805,544 | 14,597 | 4,298 |
| 1887 | 28 | 2,499 | 46 | - 38 | 1,000,000 | 333, 564, 800 | 2,273,566 | 17,262 | 5,368 |
| 1888 | 24. | 3,568 | 45 | 42 | 3,000,000 | 439,388,950 | 2,051,128 | 15,638 | 12,406 |
| 1889 | 29 | 4,400 | 46 | 84 | 2,500,000 | 555, 319, 800 | 3, 327, 030 | 24,359 | 25,859 |
| 1890 | | 4,368 | 52 | 27 | 2,500,000 | 533, 686, 156 | 2,939,217 | 20,339 | 21,173 |
| 1891 | | 2,985 | 54 | 13 | 1.775,000 | 355, 138, 873 | 1,946,642 | 12,608 | 15,069 |
| 1892 | | 2,002 | 55 | 10 | 1,756,000 | 223, 623, 750 | 1,329,644 | 8,400 | 10,815 |
| 1893 | | 2,235 | 57 | 27 | 1,721,000 | 366, 406, 625 | 1,269,002 | 13,150 | 15,465 |
| 1894 | 44 | 2,356 | 56 | 28 | 2,000,000 | 533, 361, 900 | 1,999,506 | 20,057 | 27,582 |
| 1895 | 42 | 2,276 | 48 | 35 | 1,600,000 | 461,747,000 | 1,767,754 | 18,682 | 21,965 |
| 1896 | | 2,115 | 53 | - 38 | 1,376,500 | 401, 425, 800 | 1,741,530 | 14,280 | 21,484 |
| 1897 | | 2,750 | 60 | 45 | 1,871,000 | 584, 302, 930 | 2, 147, 113 | 18,430 | 34,372 |
| 1898 | 40 | 2,470 | 51 | 20 | 2,500,000 | 542,500,000 | 2,450,000 | 17,360 | 34,120 |

The following summary shows the extent of the menhaden industry according to the latest returns of the United States Fish Commission. The figures for Connecticut, New Jersey, and Virginia for 1902 are not yet available, and there have been no operations in Texas since 1901:

| States. | Year. | Facto- ries. | Fish received. | Oil made. | | Dried scrap. | | Acidulated scrap. | | Total value of product. |
|--|--|--|---|--|---|---|----------|---|------------------------------|-------------------------------|
| Rhode Island Connecticut New York Delaware Virginia. North Carolina Texas. | 1902 1900 1902 1901 1902 1901 1902 1901 1902 | No. 1 2 3 6 1 15 7 1 | $\begin{array}{c} No.\\ 114,757,900\\ 19,975,700\\ 187,671,300\\ 27,090,000\\ 84,869,100\\ 378,727,331\\ 70,167,800\\ 26,806,500 \end{array}$ | $\begin{array}{r} 118,750\\ 1,397,583\\ 109,789\\ 394,119\\ 723,215\\ 102,052 \end{array}$ | 225,912 30,475 353,279 25,440 96,724 164,465 22,730 | $450 \\ 9,030 \\ 1,131 \\ 1,642 \\ 21,130 \\ 1,884$ | | $15,727 \\1,450 \\7,410 \\8,871 \\10,591 \\4,804$ | 92,765 110,668 135,388 | |
| Total | | 36 | 910,065,631 | 3, 812, 335 | 933,679 | 36,977 | 909, 505 | 48,853 | 630, 305 | 2,473,489 |

Although very small quantities of other fish are used, practically the entire catch in the menhaden fishery consists of that species alone. The principal species other than menhaden are sea-robin, skates, and bellows-fish. These are secured mostly in pound nets, especially in those set in Gardiner Bay. They sell for 50 to 80 cents per 1,000, and two or three million are used each year. The sea-robin yields

DISCHARGING MENHADEN FROM VESSEL BY MEANS OF TUBS.

DISCHARGING MENHADEN FROM STEAMER BY MEANS OF BUCKET ELEVATOR, AT PROMISED LAND, NEW YORK.

3 or 4 quarts of oil to the barrel. This oil is of good color and is readily sold for menhaden oil, but the scrap is not quite so desirable for fertilizer as that from menhaden. Skates and bellows-fish are comparatively dry, yielding less than one pint of oil to the barrel of fish.

Owing to much contention resulting from the claim that with the menhaden large quantities of choice food-fish are taken and rendered at the factories, the United States Fish Commission, in the season of 1894, made a thorough inspection of the catches made by two representative steamers of the fleet. This examination showed that in a catch of 27,965,756 fish only one-third of 1 per cent were food-fish, and only a very small proportion of this percentage was of choice and popular varieties. "As a general thing not enough desirable food-fish are taken by the menhaden steamers to keep the vessels' crews regularly supplied with fresh fish. As a rule, all the food-fish caught are eaten either by the crews or by the factory hands, but it occasion-ally happens that schools of blue-fish, butter-fish, shad, river herring, etc., are taken and more fish are thus provided than can be consumed."

The menhaden factories are distributed along the coast at points convenient to the fishing-grounds. They vary in size and equipment according to the amount of invested capital and the degree of modernness. Some are of primitive type, consisting of two or three large kettles or try-pots and a simple press, the whole, with the accompanying equipment, costing only a few hundred dollars, and are capable of handling only 300,000 or 400,000 fish annually. From that they increase in size and capacity until the amount of invested capital in a single plant reaches half a million dollars, giving a working capacity of 200,000,000 fish annually.

COOKING AND PRESSING THE FISH.

The following account of the methods of the menhaden industry represents observations and inquiries made by the writer during the last four years, and especially in the season 1901. Most of the factories were visited either in 1901 or previously, and all details in the process of manufacture were inspected. The writer wishes to acknowledge in this connection the courtesy of Capt. N. B. Church, general manager of the Fisheries Company; Mr. H. II. Luther, superintendent of the Promised Land plant of that company, and of Capt. J. F. Bussels, of the Atlantic Fisheries Company.

There are two principal processes involved in the manufacture of oil and scrap from menhaden, viz, (1) cooking and pressing the fish and (2) drying or otherwise preserving the scrap, the methods varying according to the facilities of the plant. The great bulk of the fish are handled at large factories thoroughly equipped with modern machinery, including bucket elevators, automatic conveyors, continuous steam-cookers, hydraulic presses, artificial driers, etc.

Some of the factories, especially in Virginia, are quite small, with

primitive methods of work. In one of them a fire is made under four cast-iron stationary boiling vats holding about 2 barrels of fish each. By means of a trough leading from a pump, water is permitted to run into the vats. After sufficient cooking, the fish are scooped out with large dip nets and put on a platform, whence they are pitched into tub presses having a lining of coarse canvas. By means of a vertical screw operated by a horizontal lever, pressure is applied to the mass, and the exuding oil runs through a trough to the oil vats. Another Chesapeake factory has six iron cooking-vats, in which are suspended an equal number of iron latticed baskets containing the fish. After cooking, the baskets are transferred by means of a crane and the fish placed in an hydraulic press. This method of cooking was formerly in general use all along the coast frequented by the menhaden.

In the best-equipped factories the fish are removed from the hold of the steamer, where they have been stowed in bulk, by means of a bucket elevator. This contrivance, so important in the handling of grain and coal, was not introduced in the menhaden business until 1890, when a factory at Tiverton, R. L., was equipped with one. At present, however, they are in use in all the principal factories. Before their adoption the fish were shoveled into measuring tubs in the vessel's hold, and these raised and dumped in elevated receiving bins, or into cars holding 15 or 20 barrels each and running on inclined tramways to the receiving bins, requiring five or six hours to dis charge 1,000 barrels. By using the bucket elevator, with four men to feed it, 1,000 barrels of fish may easily be discharged in an hour. This decrease in length of time required for discharging is frequently a matter of great importance when fish are abundant, as it enables the steamers to speedily return to the fishing-grounds.

The elevator dumps the fish into one of a pair of automatic weighing hoppers, with a dial-scale indicator of 1-ton capacity. When the required weight is in the hopper, by means of a lever the incoming fish are directed into the other hopper, and the bottom of the full one is dropped, thus dumping its contents into a conveyor, which deposits the fish into a receiving bin with capacity of 6,000 or 8,000 barrels.

The weighing of the fish is necessary to secure a record of the quantity received, furnishing a basis for compensating the captains of the vessels, and for other purposes. It thus appears that this method of discharging changes the standard of measurement from bulk to weight. Although it is customary to reckon the quantity of menhaden by so many thousand, the fish are not counted. An arbitrary size of 22 cubic inches is the standard measurement for each fish, or 22,000 cubic inches to the thousand. Two hundred pounds represent one barrel, and $3\frac{1}{2}$ barrels represent 1,000 fish. The size of the fish varies considerably, and the actual number required to make "one thousand" in measure ranges from 500 to 2,000 in number.

The floor of the large receiving bin slants toward the longitudinal

middle, where is stationed a trough or chute with a covering movable in sections of short length. In this trough runs a conveyor, consisting of two parallel endless chains, between which, at intervals of 2 or 3 feet, are attached pieces of board which act as buckets to push the fish along through the trough when a section of the covering is removed. This trough with endless carrier is in use in practically all the large factories, irrespective of the method of cooking. It carries the fish to the cooking bins, or to the steam cooker in case the latter is employed, traps or slides in the bottom of the trough permitting the distribution of the fish into any of the tanks desired.

The cooking bins or tanks are large rectangular wooden boxes having capacity of from 50 to 100 barrels each and arranged with a lattice platform, about 4 inches above the bottom, on which the fish rest. Between the lattice platform and the bottom there is a nest of steam piping connected with a pipe leading from steam boilers. A water pipe also leads into the bin, through which salt water for cooking the fish is pumped into the tanks to a depth of about 1 foot or more. For convenience in handling the materials, the bins are commonly arranged in two adjacent rows, and above them runs the endless carrier conveying the fish from the receiving bin. On the outer side of each of the two rows of tanks runs a track leading to the presses, to be described later. When the bins are filled with fish, steam is turned into the piping in the bottom and heats the water, thus cooking the fish, reducing them to pulp, and breaking the oil cells. The amount of the cooking determines the extent to which the oil is removed. If carried to an extreme point, nearly all the oil can be pressed out. But severe cooking results in greatly damaging the quality of the oil and in loss of a certain amount of the nitrogenous compounds so important in determining the commercial value of the scrap. It is, therefore, important that the heat be so regulated as to extract as much oil as practicable without injuring the quality and with a minimum loss of nitrogen. The requisite degree of cooking is reached when the fish crumble to pieces easily. A high degree of temperature is maintained for about fifty minutes, when the mass of fish is broken up and then permitted to simmer for four or five hours. The free oil and water are then drawn off and the fish permitted to drain for several hours.

During the last two or three years the largest factories on the coast have been using continuous steam cookers. The most popular form is constructed so that a conveyor transmits the fish into a steam-tight receptacle, into which a large number of jets of steam are introduced, which thoroughly cooks the mass. The process is continuous, requiring about fifteen minutes for the fish to pass through, and the capacity of each cooker is about 600 barrels per hour. From the cooker the mass of fish is carried by means of a screw conveyor into an upright elevator casing, whence a bucket elevator carries it to receiving tanks, where it drains overnight. These tanks are usually about 10 feet square and 5 feet deep. Most factories use for this purpose the bins used in cooking before the adoption of the steam cooker. One factory has a total of 52 tanks for draining the fish.

The oil and water draining from the cooked fish is pumped or led off through pipes or troughs into the oil room, where it is received into large vats. After draining for ten or twelve hours, the mass of cooked fish is forked out of the tanks and thrown into curbs for pressing.

The curbs are of various designs. The most common form is a cylindrical tub with a hinged bottom firmly attached to axles, which are provided with wheels so as to run on a tramway. The staves are made of metal slats and are held together by stout bands. They are set at a convenient distance apart to allow the oil and water to pass through, and increase in width from the center to the bottom enough to overcome the enlargement of the opening between the slats consequent upon their outward slant. This outward slant commences at about the middle of the curb and extends to the lower end, and its effect is to give the curb an increasing diameter as the bottom is approached, so that the hard cake remaining after pressure is relaxed can be readily forced out at the bottom. Through the center of the curb runs a hollow core, stoutly constructed of metal slats. The bottom is attached by means of hinges to the lower end of braces, which are firmly fastened to the lower band of the curb, the axle, and the middle band. The opposite side of the bottom is suspended by means of latches which are caught and held by a bolt sliding freely within the braces and actuated by a lever pivoted upon the axles. The axles are also braced by stays on either side of the tub, which pass from one axle to the other, and, being curved to fit closely to a section of a band, are firmly attached thereto. The capacity of each curb is about 7 barrels. A metal shield surrounds it to protect the workmen from the spattering oil and water when pressure is applied.

The curb, having been filled with cooked fish, is run along the rail and placed under a solid stationary head made to fit closely inside the curb and against which the fish are pressed as the curb is slowly raised by a powerful hydraulic press. This forces out most of the remaining oil and water, which exudes from between the slats, and by means of troughs and pipes is conveyed to the oil room. On relaxing the pressure the curb resumes its position on the railway and is moved from the press stand and the core removed; the bottom is swung out of the way, and the hard cake remaining in the tub is forced through the bottom, falling into receptacles underneath.

Under ordinary conditions from 5 to 7 per cent of the oil is left in the pressed fish, it being difficult to remove all the oil and water, owing to the gelatinous or gluey state of the fish as a result of the cooking. In some factories the chum or pressed fish is washed with hot water and then repressed, but this is scarcely profitable if the first pressing is properly performed. The chum now passes to the scrap room and its further treatment is described on pp. 265–268.

About two-thirds of the total amount of oil obtained runs from the cooked fish while it drains in the vats, the remaining one-third being extracted by the presses. The former is a trifle better than the latter, as it is somewhat lighter in color. The two grades are sometimes kept separate, but such is not the general practice.

Among the many methods of extracting the oil which have been tried but not adopted is the use of fumes of benzine or bisulphide of carbon. When these are brought in contact with the fish in air-tight chambers, they absorb the oil, the liquid result collecting in tanks at the bottom of the receptacle and the benzine being subsequently expelled by evaporation.

Much attention has been paid to devising a continuous process of cooking and pressing, in which the elements of labor are reduced to a minimum. When the Stanley process was invented, about five years ago, it was thought that the problem was solved and the patent rights were sold for a very large sum of money. In this process the fish are cooked in boiling water in a large, comparatively shallow, semicylindrical tank, the lower portion of which is fitted with a worm conveyor, while near the top is a perforated plate or grating, above which the fish or other solid matter can not pass, but through which the water and oil rise. The material is fed in through a hopper at one end and is discharged at the other end, being carried forward by the worm conveyor, which also reduces the material to a finely divided state, thus enabling the action of the water upon all parts of the material freely to liberate the oil. The oil rises to the surface of the water in the cooking vessel and escapes through a pipe in the end into a settling tank. From the bottom of this tank whatever water has come over with the oil is pumped back into the cooking vessel. entering at the opposite end from the outlet through which the oil flows and at a point near the surface of the level at which the water in the boiler is constantly kept, thus creating a current which carries the oil constantly forward toward the outlet. The scrap from which the oil has been liberated is carried forward to an outlet in the bottom. of the cylinder by the worm conveyor and falls into an upright elevator casing having elevator buckets running upon an endless chain, which carry the material up and over, dumping it into a receptacle suitable for removing for further treatment. The liquid matter is carried up by the elevator buckets, drains through them, and returns to the liquor in the cooking apparatus. This process, however, has not yet been found sufficiently practical for general adoption.

As long ago as 1858 the Ocean Oil and Guano Company, of Southold, N. Y., used a steam cylinder cooker somewhat similar to the continuous cooker now in use. This is said to have been invented by a Frenchman named De Molon, and is described in a pamphlet issued by the above company in 1860 as follows: The raw fish, in quantities of $1\frac{2}{3}$

tons, are placed in the inner chamber of a revolving cylinder, with double walls, the space between the inner and the outer walls being filled with steam at about 80 pounds pressure. Before admitting steam the cylinder is put in motion, so that as it revolves each fish is constantly changing its position. A uniform temperature is maintained by means of one head of the inner cylinder being perforated to permit the steam generated in the mass to escape through a safety valve.

In the oil room of the menhaden factories is a series of receptacles into which the oil and water are received from the draining tanks and the presses. The combined mass of oil and water is first subjected to a temperature of 150° F., which causes them to separate, the oil rising to the surface. It is permitted to overflow to other tanks containing hot water, where it is brought to the boiling-point by means of injected steam. It is important that the oil be separated from the water before the impurities begin to ferment, fermentation causing it to be dark and of lower grade. After settling for a while the oil is withdrawn into another tank and thence pumped into the storage tanks.

A contrivance for withdrawing the oil from the surface consists of a jointed pipe with open end at top, which in some cases is funnelshaped. This passes up through the bottom of the vat, and the top of the pipe is so arranged that it may be raised or lowered to any desired distance beneath the surface to receive and guide the surface oil into the next vat. Sometimes there is a series of as many as 5 vats, from one to another of which the oil passes, each time becoming purer and purer as it is cooked and drained. The oil is led into the first of the cooking vats through the bottom, the pipe leading nearly to the surface. A second pipe passing through the bottom and terminating with an open top not a great distance above the bottom **carries** off the water-oil or less pure oil as it settles and conducts it to near the top of the second vat, where the oil and water are further separated.

At the bottom of each settling tank is deposited a quantity of finelydivided fleshy substance known as "gurry." This is removed from the tanks to the gurry room, where it is treated or sprinkled with sulphuric acid to facilitate the separation of the oil from the flesh fiber. It is then placed in bags, 2 gallons to the bag, and these placed in pairs under a press and subjected to great pressure, resulting in a small quantity of oil. The residuum in the bags, consisting of a hard cake, is broken up and either discarded or mixed with the scrap.

When thoroughly separated from the water, the oil is pumped into suitable storage tanks or barreled. The refining or bleaching of the oil is rarely done at the factories, but is performed by the oil-refiners of New York, New Bedford, Boston, etc., and the methods and results have already been described on p. 234.

The yield of oil varies greatly, ranging from less than 1 pint to as much as 15 gallons or more per thousand fish, or rather for each 22,000 cubic inches of fish. As a rule, it is much greater in the autumn than in the spring, and also greater in Northern than in Southern localities. Even in the same locality the fish are very much fatter throughout some years than in others. For instance, the average yield of the fish taken in Chesapeake Bay in 1887 was nearly 6 gallons to the thousand, whereas in 1888 it was a little over 2 gallons, and early in that season it was less than 1 pint to the thousand fish. Some years ago one of the Shelter Island factories secured from one lot of fish a yield of 24 gallons to the thousand. The largest yield brought to the notice of the writer was derived from some menhaden that had been inclosed in Shinnecock Bay late in autumn. By feeding in the brackish water of that bay these became so fat that they yielded at the rate of 48 gallons of oil per thousand fish. Considering the entire Atlantic coast for a series of ten years ending in 1898, it is found that each thousand fish yielded 4.59 gallons of oil and 138 pounds of scrap containing 10 per cent of moisture. During the ten years ending in 1888 the yield per thousand fish was 4 gallons, and during the six vears ending in 1878 it was 5.26 gallons.

The table given on page 233 shows the total yield of menhaden oil on the Atlantic coast of the United States and the average yield per thousand fish for each year since 1873. From those figures it appears that the largest yield per thousand fish was 6.84 gallons in 1874. The yield in 1887 and also that in 1886 were large, being 6.81 and 6.38 gallons, respectively. The smallest yield per 1,000 fish was in 1880, 2.62 gallons, and in 1881, 2.79 gallons.

Not only does the yield of oil vary from year to year, but it also differs greatly in different sections of the country. As a rule, the Northern fish, or rather those taken in Northern waters, especially off the Maine coast, are the fattest, while those from off the southern coast yield the smallest quantity. In the year 1900, for instance, the yield of oil at the Rhode Island factories was 5.76 gallons per 1,000 fish; in New York it was 6.39 gallons; in Delaware 4.92 gallons, and in Texas 3.51 gallons to the 1,000 fish. The menhaden taken off the coast of Maine are by far the fattest, and in the few seasons when fish are obtainable there the menhaden fishermen from other States hasten to that coast. In 1888 the Maine fish yielded 11.85 gallons of oil per 1,000; in 1889, 10.83 gallons, and in 1898, 9.73 gallons to the thousand measure. Menhaden have not been taken to any extent on that coast since 1898.

TREATMENT OF THE SCRAP.

As it leaves the press, fish scrap contains 45 or 50 per cent of water, which can not be removed by compression owing to the gelatinous condition of the fiber. Although suitable for immediate application as a fertilizer, the moist condition of this scrap renders it unde-

sirable for economic transportation or for storage for a great length of time, and necessitates further treatment. Previous to 1875 most of the scrap was sold in a green state, just as it came from the press, but since 1878 practically all of it has been dried or treated with sulphuric acid.

Formerly in drying it was customary at all the factories to spread the green scrap upon platforms, where it was exposed to the action of the sun for several days. While this is the common method at present, most of the large factories have discarded it and are using artificial driers. The platforms are made of tight or matched boards laid flat upon a stout framework or upon the level ground, and are sometimes of large area, covering 2 or 3 acres. The scrap is transferred from the bin beneath the presses by means of screw conveyors and carried to a receiving bin, where it is dumped into hand carts with capacity of one-half ton each and carried to the platform. It is there spread to a depth of from 3 to 6 inches and is frequently turned or raked over, so as to expose all particles to the sun's influence. In threatening weather and when the night dews are heavy, the scrap is raked into windrows or heaps and, if necessary, covered with canvas to protect it from moisture. After two or three days' drying it is piled in heaps and left to sweat for a time, and then is again spread to evaporate the free moisture generated in the heaps. This second drying reduces the amount of moisture in the scrap to about 10 per cent. and the material may be safely bagged and stored for market, though that operation is usually deferred until immediately before its shipment. Frequently the dried scrap is ground, especially when it is to be sold direct to the farmers without further treatment, in order that it may be sown in drills with wheat and other grains.

If good weather could always be depended on, platform-drving would possibly be the most economical and satisfactory method; but owing to uncertainties of the weather much difficulty is frequently experienced in this process, resulting in a great waste of material and extra expenditure of labor and loss of ammonia in the scrap. This has resulted in the adoption of artificial driers at the largest factories. Several forms of apparatus have been employed, but the principle in most of them is similar, the scrap being subjected to a current of heated air by means of a blower. The drier adopted in the largest factories consists of an iron cylinder about 30 feet long and 5 feet in diameter, so mounted as to revolve horizontally. On the interior surface are shelves or paddles which, as the evlinder revolves, lift the scrap fed in at one end and permit it to fall to the bottom. A strong current of heated air is forced through the cylinder, extracting the moisture and gradually driving the scrap out at the further end.

Another form of drier in use consists of a large double cylinder of iron set on an incline, into which the scrap is fed through an opening at the higher end and guided along to the lower end by means of a revolving screw. The space between the inner and outer walls of the cylinder is filled with steam, which heats the scrap, thereby evaporating most of the moisture.

Labor-saving devices make the handling of the scrap almost automatic. From the presses it is transferred to the drier by means of screw conveyors and bucket elevators, and is fed intermittently in quantities of 200 pounds at intervals of 45 to 60 seconds. The capacity of a drier is $2\frac{1}{2}$ to 3 tons per hour, and the largest factories usually have 2 drying machines. From these the scrap is conveyed to the storage room.

Although the term "dried" is popularly applied to all scrap from which a large portion of the moisture has been removed by evaporation, its use in a technical sense refers to scrap containing not to exceed 12 per cent of moisture. In modern factories, green scrap fresh from the presses contains from 45 to 50 per cent of water. When desiccated so that only 10 per cent of its weight is water, each ton of chum or green scrap yields about 1,156 pounds of "dried scrap." It is not always that so large a quantity of water is eliminated, and sometimes the finished scrap contains 25 and even 35 per cent of moisture. Owing to its tendency to lose nitrogen in the form of ammonia and its unsuitability for storage or transportation, the scrap containing a high percentage of moisture is for use principally in the vicinity of the factories.

Not all the scrap, however, is dried, a large percentage being treated with sulphuric acid for the purpose of "fixing" the ammonia, preventing fermentation, and dissolving the bones. To every ton of scrap, from 80 to 200 pounds of sulphuric acid of about 50° strength is added and thoroughly commingled, the quantity of acid used depending to some extent on the state of the weather and the extent of decomposition of the fish. This is conveniently done by depositing the green scrap in handcarts of 1,000 pounds capacity, wheeling these to an elevated platform and dumping the contents beneath, when the heap is immediately sprinkled with about 60 pounds of sulphuric acid contained in a leaden pot. After a short while the bones dissolve and the former grayish color. The ammonia is fixed by the acid and the tendency to decomposition overcome. The scrap is then conveyed to the storage room and shipped in bulk as required.

Instead of sulphuric acid, the solid granular sodium sulphate has been used to mix with the serap, about 90 pounds being thoroughly combined with each ton. While this method is somewhat cheaper than applying sulphuric acid, it is not so satisfactory, and sodium sulphate is now little used for this purpose.

Owing to the difficulty in drying the scrap, most of that prepared at the Northern factories is acidulated, while the bulk of the Southern product is dried. In the last year for which data are available, the product of the entire coast was 48,853 tons acidulated and 36,977

tons dried, with a total selling value of \$1,539,810. Of the 45,711 tons produced from Delaware northward, 33,458 tons were acidulated and 12,253 were dried, the average price of the former being \$12.87 per ton and the latter \$26.22 per ton. South of Delaware the product of green and of acidulated scrap combined, according to the latest returns, was 15,395 tons, while 24,724 tons were dried, the respective values per ton being \$12.95 and \$23.79.

Only a small percentage of the fish scrap is used by the farmers in the condition in which it leaves the factories; most of it is ground and serves as an ingredient in compound or so-called "complete" fertilizers. Compound fertilizers are prepared at some of the menhaden factories, but as a general thing their preparation is in the hands of persons who have nothing to do with eatching and rendering the fish.

The value of commercial fertilizers is dependent mainly on their content of nitrogen and phosphoric acid, which are the most important plant foods usually lacking in the soil. The nitrogen necessary is supplied mainly by fish scrap. Various other materials are also used, as dried blood, meat scrap and other slaughter-house refuse. cotton seed, sulphate of ammonia, nitrate of soda, Peruvian guano, etc. The phosphoric acid is supplied by fish scrap to some extent, but principally by the phosphate rocks, boneblack from the sugar refineries, bone meal, etc., the solubility of the phosphate being increased by treatment with sulphuric acid, thus making superphosphates. The value of fish scrap varies according to the percentage of ammonia and phosphoric acid contained therein. As a general rule, dried scrap contains about 8 per cent of nitrogen and 84 per cent of phosphoric On a selling basis of \$24 per ton, the nitrogen costs about 10 acid. cents per pound and the phosphoric acid about 34 cents per pound for compounding purposes. Other necessary plant foods are potash, lime, magnesia, sulphuric acid, and iron. These usually exist in sufficient quantities in the soil itself, but are added under special conditions, especially the potash. The nature of the ingredients and the respective proportions required vary according to the soil and the crop for which the compound is intended.

Although the agricultural value of dried fish scrap is nearly equal to that of Peruvian guano, the market price is much below that artiele. In explanation of this fact it may be stated that fish scrap is not in such compact and good mechanical condition for shipment and general use. Its value as a fertilizing agent has not been so widely known as that of Peruvian guano, and thus its principal use is largely limited to the manufacturers of superphosphates, who are forced by competition to exercise great caution in the cost of manufacture. And, furthermore, there is a tendency to reduce the quantity of ammonia and increase that of phosphoric acid and potash in complete fertilizers to meet the requirements of the soil. Other ammoniated materials now compete with fish guano in the making of superphosphates, among

ARTIFICIAL DRIER IN FACTORY OF FISHERIES COMPANY, PROMISED LAND, NEW YORK. ISEE P. 266.1

FERTILIZER ROOM IN FACTORY OF THE FISHERIES COMPANY, FROMISED LAND, N. Y.

which are cotton seed, sulphate of ammonia, nitrate of soda, tankage, meat scraps, slaughter-house refuse, etc.

The product of fish scrap, reduced to basis of dried weight, produced from 1873 to 1900 approximates 1,048,000 tons, or an annual average of 37,428 tons. As it is estimated that in a ton of compound fertilizer ready for the soil the usual proportion of fish scrap is 25 per cent, it is seen that the industry has contributed the ammoniate for 4,192,000 tons of fertilizer, or at the rate of 149,712 tons annually. In growing cotton, for which these fertilizers are largely used, 250 pounds are generally employed to raise one bale.

FERTILIZERS FROM FISH WASTE OR REFUSE.

Even in the food-fisheries large quantities of materials are obtained which can not be used for food. This includes not only non-edible species, but also those edible varieties which are not marketable, owing to such unusual conditions as lack of transportation facilities or a glut in the market. It likewise includes the refuse in dressing fish for the markets and for canning, drying, salting, etc.

Formerly, when the markets were overstocked during warm weather. large quantities of fresh fish spoiled and were suitable only for fertilizer. Even so choice a variety as the mackerel has been used for enriching land when taken in larger quantities than could be used for food purposes. In 1880, for instance, when the total catch of mackerel in New England approximated 132,000,000 pounds, 500,000 pounds of small fish were reported as having been used in Massachusetts as fertilizer.a

Previous to 1870, according to Capt. N. B. Church, many thousand barrels of scup and sea bass, taken in trap nets between Cape Cod and Montauk Point, were purchased by the farmers and spread on the land. Mr. A. B. Alexander states that large quantities of shad taken in the Columbia River are used for fertilizer. With the development of fish freezers and the improved means of communication and transportation this waste is much reduced. Yet the aggregate quantity of food-fish received in bad condition, or which "goes bad" in the markets, in the course of the year is very large in any populous city. During 1899, according to the Fish Trades Gazette, the quantity of fish condemned by the officers of the Fishmongers' Company in London was 1,520 tons, of which 232 tons were plaice, 228 tons Norwegian herring, 169 tons haddock, 94 tons mussels, 80 tons skate, 70 tons welks, and 60 tons of periwinkles. In New York City the quantity of spoiled fish condemned during the summer amounts to several hundred thousand pounds each year.^b

^a Report U. S. Fish Commission. 1881, p. 219. ^b During the interval between Wednesday, June 30, and Wednesday, July 14, the authorities of the health department of New York City condemned as unfit for food 41,650 pounds of fish. Of this amount, 39,650 nounds were soized in the Fulton Fish Market, the remaining 2,000 pounds being condemned by the local inspectors among the retail dealors in various sections of the city. (The Fishing Gazette, 1902, p. 458.)

Before the development of the sardine industry in Maine, the small fish taken in connection with the smoked-herring business were commonly converted into oil and fertilizer. After the oil had been extracted by boiling and pressing, the chum was broken up, spread on a board platform, and dried by the action of the sun. It was then ground, bagged, and sold at \$12 to \$16 per ton.

About fifteen years ago a factory was established at Pillar Point, on the shore of Lake Ontario, for converting the surplus alewives occurring in that lake into fertilizer. The fish, obtained by means of seines and pound nets, were cooked for about 20 minutes in steam chests, permitted to drain for an hour, and then subjected to pressure in circular curbs holding about 5 barrels of chum each. The scrap was dried and ground and sold to the farmers for about \$20 to \$25 per ton. It is reported that in 1886 1,000,000 fish were utilized, yielding 500 gallons of oil and 63 tons of fertilizer. Along the shores of the Great Lakes and other waters, quantities of dead fish have been washed up in windrows, furnishing a harvest for the farmers in the vicinity.

In the pound-net fisheries of Cape Cod many skates and other "poor" fish, taken incidentally with the food-fish, are converted into fertilizer. If these contain much oil, it may be extracted by boiling and pressing. Ordinarily, however, the fish are dried without previous treatment. Especially is this the case with skates, which in some instances are suspended in rows above the ground until thoroughly dry, and are then ground fine. A large quantity of these fish hanging from a series of flakes or rails presents a very curious sight.

The quantity of waste and spoiled fish, however, is small compared with the very large amount of viscera and other offal resulting from dressing fish. The decrease in weight in dressing ranges from 15 to 35 per cent of the round weight, according to the species of fish and the season of the year. Assuming an average decrease of 25 per cent, it appears that in dressing the 900,000,000 pounds of food-fish produced in the United States each year the refuse amounts to 225,000,000 pounds, or 112,500 tons. While this is a very large amount in the aggregate, it is so widely distributed that the quantity at any one place is not of great importance, and usually its disposal is a sanitary problem rather than a source of revenue. In dressing fish at sea the waste is almost invariably thrown overboard. In the cities this material is usually combined with and handled in the same way as other market refuse. At the canneries where large quantities of fish are dressed, as in the salmon canneries of the Pacific coast, and the sardine canneries of Maine, the refuse is now in many cases rendered into oil and fertilizer. This has already been noted in the chapter on the preparation of oils from waste products in the fisheries. (See pp. 240-242).

In case the fish dressings contain little oil the inducements for utilizing them are not great. Water constitutes a very large proportion of the viscera, the quantity ranging from 65 to 90 per cent,

AQUATIC PRODUCTS AS FERTILIZERS.

according to the species and the season. Even when the moisture is largely removed the quantity of fertilizing substances in the dried material is small. However, if the quantity of oil in the waste is sufficient to pay the cost of its extraction, it is usually profitable to perform the slight additional labor necessary to make the material suitable for fertilizer. The manurial content of fish heads is relatively large, and whenever they are accumulated in large quantities their conversion into fertilizer is profitable.

A convenient process of converting a small quantity of refuse from dressing fish into fertilizer is to store it in a receptacle made in the ground. This should be about 5 or 6 feet deep, with the area depending on the amount of refuse, but usually about 6 feet square. It should be dry and if the soil is sandy some clay should be spread at the bottom. First is placed a layer of wood ashes a few inches deep and then an equal layer of fish refuse covered by a sprinkling of lime. Then follow another layer of ashes, one of fish refuse sprinkled with lime, and so on until the hole is full. It should be covered with earth or sod and these covered with weighted boards and permitted to so remain for several months. The fish refuse quickly disintegrates and becomes mixed with the ashes, forming an excellent fertilizer.

Since 1875 the skins and bones resulting from the preparation of boneless codfish have been used for fertilizing purposes. After desalting them and extracting the glue, the remaining material is dried and sold for \$15 or \$20 per ton. The annual product amounts to about 3,000 tons. Most of this is produced at Gloucester, Mass., with smaller quantities at Boston, Provincetown, Portland, and Vinal Haven. According to analyses, this fertilizer contains about 10 or 12 per cent of phosphoric acid, 8 or 9 per cent of nitrogen, and 5 or 6 per cent of moisture.

The refuse in preparing oil from livers of cod, sharks, and related species, from heads of halibut, sturgeon, and sword-fish, and from other materials is also dried and sold for fertilizer. The liver scrap formerly sold at \$8 or \$10 per ton, but at present its market value is only about half of that amount. Fertilizer made from fish heads is especially rich in phosphoric acid. A sample of guano made in Boston from fresh cod heads showed 20 per cent of phosphoric acid, $6\frac{1}{2}$ per cent of nitrogen, and $3\frac{1}{2}$ per cent of moisture, and a sample of that made from fresh halibut heads contained 13 per cent of phosphoric acid, $5\frac{1}{3}$ per cent of nitrogen, and 5 per cent of moisture.

An important fish fertilizer in Norway is made from the refuse in dressing cod for drying, consisting principally of heads and backbones. These are merely dried by spreading them on the rocks and are then broken and ground to the condition of coarse bone-meal. In some localities the refuse is first steamed, to facilitate the drying and grinding. The utilization of these materials for fertilizer was begun about 1855, and the industry is centered at the Lofoden Islands, the location of the principal cod fishery of Europe. The present

annual production is said to be upward of 10,000 tons of prepared scrap, about 20,000,000 cod heads being utilized for the purpose.

According to a report made by Consul-General Crowe, of the British service, the heads and bones are first partly dried in the open air and then cut into small pieces and thoroughly dried in a kiln. When all but 12 or 15 per cent of moisture has been driven off, the materials are crushed and then ground between millstones to the fineness of corn meal. The heads and bones are crushed separately, but are mixed together before the grinding process, the usual proportion of the mixture being one part of the backbones to five parts of the heads. Chemical analyses indicate an average content of water 13 per cent; organic substances 49.3 per cent, of which 8 per cent is nitrogen and 7.6 per cent anmonia; and inorganic substances 37.7 per cent, of which 14.9 per cent is phosphoric acid.

In utilizing whales at the Norwegian stations established in connection with the taking of these cetaceans, the flesh and bones are commonly prepared as fertilizer after the extraction of the oil. The blubber and the fat-lean are first removed from the flesh for oil-rendering, and then the flesh is cut into strips or minced in a machine and boiled with steam under pressure. As described by Michael Winnem, in *Chemische Revue*, the receptacles for boiling the flesh are horizontal iron cylinders provided with close-fitting openings. They are also provided with two outlet pipes, one at the very bottom, for removing the water, and the other about 4 inches higher up, for drawing off the oil. The flesh is spread on three superimposed perforated travs or false bottoms, and subjected within the evlinder to steam at a pressure of 40 or 50 pounds to the square inch for ten or twelve hours. At the end of that period the flesh is removed and placed in drying ovens. These are built of brick, 20 to 25 feet high, and fitted with internal sheet-metal travs, which are mounted alternately on the sides of the oven and on a central revolving shaft. The latter carries a number of slanting scrapers which revolve once in 5 minutes and slowly force the flesh from one tray to the next lower ones in succession. The descending flesh is dried by the heated air from a coke fire, which enters the oven at the top and passes out through an opening at the bottom.

The process is somewhat slow, the output during twenty-four hours not exceeding 2 tons for each oven. If desired, the fertilizer may be ground in a mill. The bones are broken and treated in much the same manner as the flesh. After boiling they are crushed in a disintegrator, ground in a bone-mill, and nixed with the flesh scrap. An analysis, made by Kroeker, of Norwegian whale fertilizer indicated 7.63 per cent of nitrogen, 13.45 per cent of phosphoric acid, 16.49 per cent of lime, and 0.15 per cent of magnesia in a sample containing 5.35 per cent of moisture. The market price is about ± 5 per ton. In the bottle-nose fishery the oil is commonly extracted at sea, as in case of the American whale fishery, and consequently it is not practicable to utilize the flesh and bones as fertilizer.

AQUATIC PRODUCTS AS FERTILIZERS.

FERTILIZERS FROM CRUSTACEANS.

Among the most curious of the marine products used for fertilizer is the horseshoe crab (Limulus polyphemus), which is found in comparative abundance at several points on the Atlantic coast and especially on the shores of Delaware Bay. The use of this fertilizer dates back at least a hundred years, old records indicating its employment by the farmers of Cape Cod in the eighteenth century. It is reported that they were first used in the Delaware Bay region about fifty years ago. In that section they are taken during May and June, when large numbers visit the shallow waters for spawning purposes. During the remainder of the year they are scarce inshore, although a few may be obtained. They are secured by picking them up at night on the shore either by hand or with pitchforks, or they are taken in pound nets constructed especially for that purpose. The pound nets cost \$25 to \$75 each, and they secure by far the greater number. At present the catch is very much less than it was twenty years ago. In 1880, according to the returns of the United States Fish Commission, the total catch in Delaware Bay amounted to 4,300,000 in number. worth \$16,300. In 1890, it was only 1,939,670, worth \$8,580, and in 1897 it was still further reduced to 1,206,095, worth \$8,393. The value of the horseshoe crabs ranges from \$4 to \$8 per thousand and the weight averages about 2 pounds each.

In preparing them for fertilizer, the entire crabs are sometimes merely stacked in piles until they putrefy and become somewhat dry, when they are broken into fragments and composted with muck, lime, or other suitable materials. Two or three small factories exist at which the crabs are dried and ground, or they are ground while green and then mixed with sodium sulphate or sulphurie acid. The product sells for \$15 to \$25 per ton, and is an excellent fertilizer for grain and fruits. The output in 1880 approximated 1,950 tons, in 1890 it was reduced to 880 tons, and in 1901 it was still further reduced to 500 tons.

When lobsters were canned on the coast of Maine, a desirable grade of fertilizer was made from the shells and other refuse of the canneries. This refuse was sold at a nominal price at the factories, or given away for the hauling. The farmers collecting it would usually dry and grind it and then spread it on the land. Letters patent were issued to William D. Hall, in 1865, for the preparation of this fertilizer, but his rights in the matter were never protected. This waste is thus utilized at the present time at the lobster canneries in Nova Scotia and New Brunswick.

The shells of shrimp produced in the fisheries of California and Louisiana are used to a considerable extent for fertilizer, which is employed by the Chinese not only on the Pacific seaboard but also in the Orient. The shells are removed from the dried shrimp and sold

F. C. 1902-18

at about \$5 per ton. In California they are especially valued in strawberry and vegetable culture, while in China their principal use is as fertilizer for rice, tea plants, etc. In strawberry culture, from 300 to 400 pounds are commonly applied to each acre. It has also been used in wheat-growing, being spread broadcast on the land after the first plowing.

AGRICULTURAL LIME FROM MOLLUSK SHELLS.

The shells of oysters, clams, mussels, etc., have long been valued for agricultural purposes. All along the Atlantic coast of the United States, the extinct oyster beds, the old shell heaps, and even the living oyster reefs have long been resorted to by the neighboring farmers as a storehouse for top-dressing for their fields. In the Gulf States the most luxuriant vegetation along the shore is upon the shell mounds and marl deposits. Most of the material, however, is obtained from the shucking establishments where mollusks are opened in large quantities. Previous to the discovery of the limestone resources of Pennsylvania and other States, large quantities of shells were burned for lime; but at present their use for this purpose is confined largely to localities where the shells are unusually abundant and cheap.

An article in the *Country Gentleman*, volume 7, page 155, refers to the use of mussel shells for manure with especial reference to Essex County, Mass., as follows:

Thousands of cords of mussel shells are annually taken from the beds of the streams bordering on the sea and used on cultivated ground. I have repeatedly witnessed the value of this fertilizer in the growing of carrots and onions. The very best crop of carrots I saw the last season, more than 34 tons to the acce, had no other fertilizer applied to the land. For the last thirty years I have known it applied to lands on which onions have been grown, with a product varying from 300 to 600 bushels to the acce. It sells, delivered several miles from where it is dug, at \$4 to \$5 the cord. It is usually gathered in the winter months, taken to the shore in scows or gondolas, and thence to the fields where it is used. Sometimes it is laid in a pile of several cords together, and after it has been exposed to the frosts of winter, distributed from 4 to 8 cords to the for a time exposed to the frost.

According to Storer, "lime is not a fertilizer in itself, but is of indirect value on land in unlocking the available potash, phosphorus, and nitrogen in the soil." It also renders heavy, compact soils looser in texture and tends to bind particles of loose, leachy soils.

It is difficult to approximate the sum total of value which shells confer on agriculture, owing to the extensive use of marl deposits. Of refuse shells from shucking-houses and the like, the quantity used in this country is doubtless upward of 60,000 tons annually.

The prepared lime is generally preferred to the ground shells. Analyses indicate that the organic matter contained in shells is wellnigh free from nitrogen, and there is no evidence that it is of any use as manure. It appears, therefore, that there is no need for the expense of grinding the shells and of carting the useless constituents which can be expelled by burning. Since grinding does not reduce the material to so fine a state as burning does, the ground shell is not so active chemically.

The most popular manner of utilizing shells is to burn them and slack the product with water. The slacking may be done in heaps covered with moistened earth, and the fine powdery hydrate of lime spread directly upon the land; or the lime may be used in the compost heap; or the quicklime may be left to become air-slacked by exposure to the air, and the product be applied to the land instead of leached ashes.

AQUATIC PLANTS AS FERTILIZERS.

Although it does not appear that the many properties of aquatic plants have been fully exploited, their uses are far more numerous and diversified than is generally supposed. Their most widely known economic value is as furnishing thousands of tons of fertilizer and a great variety of nutritious and wholesome foods. In addition thereto, they are utilized in the production of many chemicals, especially iodine and bromine, and as a constituent in glues and gelatines, and as a basis for trade fruit-jellies. They also serve in sizing fabrics, in refining beer, as a mordant in dyeing, as composition in cement for covering boilers, for stuffing upholstery, packing porcelain, in making paper, fishing-lines, ropes, buttons, handles for cutlery, as tents in surgical operations, etc. The gathering of seaweeds in Great Britain early in the present century is said to have given employment to about 100,000 persons, the product being used in the manufacture of carbonate of soda.

On the coasts of France and the British Isles thousands of tons of seaweeds are collected annually for fertilizing the crops. In China and Japan they have been used as fertilizer for many centuries, but in recent years the employment of seaweeds for this purpose has been much reduced, owing to their more extended use as food and in the chemical and manufacturing industries. In the New England States they are probably the most important fertilizing material used on those farms immediately adjoining the sea. According to Storer, with the exception of the farms of the Connecticut Valley and those enriched by fish scrap or by manures received from the cities, "the only really fertile tracts in New England are to be found back of those sea beaches upon which an abundant supply of seaweeds is thrown up by storms." In the Middle Atlantic States the use of seaweeds as fertilizer is not so extensive, but in the aggregate very large quantities are employed. Elsewhere in the United States their use is of less importance.

There are three principal groups of aquatic plants used in this country for fertilizer, viz, rockweeds, kelp, and eelgrass or grass rack. Rockweeds are the large dark-colored plants furnished with small bladders or snappers, which constitute at least 75 per cent of the

covering of rocks and stones between high and low water marks on the coast from Nova Scotia to New York. There are two prominent species of these, the round-stalked and the flat-stalked. The principal species of kelp, viz, the ribbon-weed and the broad ribbon-weed or devil's apron, are common on the rocks at and below the low-water mark from Newfoundland to the New Jersey coast. In the north of Europe both of these species are used for food to a considerable extent. Dulse, Irish moss, and other species may also be used for fertilizer, but the quantity obtained is so small that they are of little importance in this connection.

The principal fertilizing agencies in aquatic plants are nitrogen and potash; the quantity of phosphoric acid is very small, amounting to only about 10 per cent as much as the above two combined. Seaweeds also contain considerable quantities of lime and magnesia. By the addition of some material containing a large percentage of phosphoric acid, as bone meal, for instance, a "complete fertilizer" is formed. This is frequently very important in order to secure the full value of the nitrogen and potash contained in the seaweeds.

According to analyses made by the Rhode Island Agricultural Experiment Station,^a the average percentage of fertilizing constituents and of water contained in various aquatic plants in the fresh state collected at different seasons on the coast of Rhode Island is as follows. For convenience of comparison, analysis of average barnyard manure is appended.

| Materials. | Nitrogen. | Phosphoric acid. | Potash. | Water. |
|--|--|---|--|--|
| Rockweed, flat-stalked Rockweed, round-stalked Broad ribbon-weed, or devil's apron Ribbon-weed, keip, or tangle Dulse Irish moss Eelgrass Barnyard manure | $\begin{array}{c} Per \ cent. \\ .88 \\ .24 \\ .23 \\ .17 \\ .37 \\ .57 \\ .35 \\ .49 \end{array}$ | $\begin{array}{c} Per \ cent. \\ 12 \\ 08 \\ 06 \\ 05 \\ 13 \\ 07 \\ .32 \end{array}$ | $\begin{array}{c} Per \ cent. \\ . \ 65 \\ . \ 64 \\ . \ 31 \\ . \ 16 \\ 1. \ 07 \\ 1. \ 02 \\ . \ 32 \\ . \ 43 \end{array}$ | Per cent. 76.55 77.26 87.50 87.99 86.25 76.03 81.19 |

The total quantity of the fertilizing ingredients in plants is very small in proportion to the weight of the material, this being due principally to the large content of water. Usually at least 75 per cent of the weight of aquatic plants consists of water, and about 80 per cent of the remainder is a soft, easily decomposable form of organic matter. The plants decompose rapidly, and the water separates from them quickly, the weeds left in heaps on the beach being reduced to onehalf or one-third of their original bulk in a few weeks. Since much of the fertilizing constituents, especially the nitrogen, wastes away in this process, it is important that the plants be used within as short a time as practicable after they have been collected. For the same reason it is much better to collect weeds directly from the rocks, or

^aBulletin No. 21 of Rhode Island Agricultural Experiment Station, January, 1893.

those just thrown up by a storm, rather than those which have lain on the beach for a considerable time.

The large content of potash makes sea plants, particularly rockweeds, especially favorable to the growth of clover. Storer refers to the abundant natural growth of red clover upon the tract of country back of Rye Beach, Maine, which has been manured with these plants since the settlement of the country. Seaweeds are also excellent for wheat, and are used for parsnips, turnips, and to some extent for potatoes, although it is claimed that they impart a somewhat unpleasant flavor to the last-named. The general opinion in this country is that potatoes grown with seaweeds are much less liable to be affected by seab than those grown with barnyard manure, but they are less mealy and of inferior flavor.^a Seaweeds have been strongly recommended for tobacco-culture, but owing to their effect on the quality of the leaf, they are not much used for this purpose. They are also highly recommended for cauliflower and cabbages. They act very quickly, and the effect of their application is confined largely to the season in which they are used, having little action upon the second and succeeding crops.

Owing to their small content of fertilizing materials and the large amount of moisture, aquatic plants are usually rather expensive for fertilizer if long eartage is required, at least 4 tons of water being transported for every ton of dry material. This limits their value to the immediate vicinity of the beaches, and they are rarely used on land more than 10 or 12 miles from the coast.

However, the manurial value of seaweeds must not be regarded merely from the point of view of the fertilizing agencies which they contain. They have a mechanical action on the soil, tending to make it friable and binding its constituents together; but the manufacture of soil is rather expensive where there is so much good land available as in this country. They have an advantage over barnyard manure in the freedom from seeds of land weeds. Formerly it was considered desirable to apply the material in the form of a compost with lime or gypsum, but experience of recent years indicates that it does not pay as a rule to compost them, except possibly in case of eelgrass and also rockweeds, to be applied as a summer or autumn top-dressing for grass land.^b The usual practice in applying them is to plow the seaweeds into the soil or to spread them upon the land as a top-dressing, the plants being in either case in as fresh a state as practicable. They also tend to prevent the crops from suffering from summer droughts, grass fields dressed with seaweeds frequently remaining green when adjacent fields are suffering.

So important is the crop of seaweeds in the Channel Islands that special laws are enforced to govern their collection and distribution. The cutting of weeds from the rocks is restricted to certain seasons comprising about four or five weeks each year. Those cast up on the

[&]quot;See Bulletin No. 21 of Rhode Island Agricultural Experiment Station, p. 20. b Ibid p. 8.

shores by the action of the waves are collected throughout the year and especially during stormy weather, furnishing employment to a large proportion of the inhabitants of Guernsey and Jersey. They are applied to the land not only in a green state, as in this country, but are also burned on the beach and on the cottage hearths and the ashes used as fertilizer.

Large quantities of seaweeds are also burned on the coast of France, especially in Brittany and Normandy, and on the coasts of Ireland and Scotland. In this process the plants are usually treated for the obtainment of iodine and salts of potassium and sodium, leaving the potash salts as the principal fertilizing agent. Although greatly reduced, owing to the production of iodine from South American caliche, the quantity of iodine made from the ashes of seaweeds is yet very large. The ashes of seaweeds are not used as fertilizer to any great extent, if at all, in this country, owing to the fact that, in burning, the valuable nitrogen is driven off and lost. However, for use at a greater distance than 12 or 15 miles from the coast it might be found practicable to burn them if this can be done with a small expenditure.

Several unsuccessful attempts have been made in this country to establish a profitable business in preparing commercial fertilizer from seaweeds. About thirty years ago a factory was built for this purpose at Boothbay, Me. Dried seaweeds were ground in a mill formed of 40 circular saws, 20 having teeth and 20 without. These were placed alternately on an iron shaft and so adjusted as to revolve in a concave trough fitted with 40 steel plates. The shaft weighed 1,000 pounds and made upward of 2,000 revolutions per minute. With this apparatus 3 tons per hour of the thoroughly dried seaweeds could be reduced to about the fineness of oats. There proved to be an insufficient market for the fertilizer, and its manufacture was discontinued in a few years.^a Most of it was sold in Connecticut for the use of tobacco-growers. The average price at the factory for the prepared material was about \$8 per ton.

Notwithstanding its relatively large content of nitrogen, phosphorie acid, and potash, as revealed by chemical analysis, eelgrass is of very little value as a fertilizer, owing to the difficulty in making those constituents available. According to Storer's well-known work on fertilizers (pp. 167–168, vol. 2):

Eelgrass taken by itself has little or no fertilizing power. It will hardly rot anywhere, either in the ground, in the hogsty, or in the manure or compost heap. It is a distinctly inconvenient thing, moreover, to have in the way of the plowshare or the dungfork. It has long stood as a kind of reproach among the vegetable manures, much as leather scraps stand in the list of animal products. For mulching for covering bins or piles of roots as protection against frost, moldiness, and decay, and for banking up in autumn around stables, greenhouses, cisterns, cellars, and pumps, eelgrass has been found useful, and this is about all

^a See The Fishery Industries of the United States, Sec. II, p. 69.

that could have been said in its favor until very recently. Considered as a manure, it was rejected by the farmers long ago. It has been tried and found wanting by numerous generations of men. Still, on analysis it appears that eelgrass contains a considerable proportion of fertilizing matters, and there can be no doubt that it will be found amenable to proper treatment and will eventually be prized as a manure. Besides 14 per cent of nitrogen, air-dried eelgrass contains 1 per cent of potash and 0.25 per cent of phosphoric acid. The ashes of eelgrass contain 7 per cent of potash and 14 per cent of phosphoric acid, which is about as much as is contained in ordinary house ashes from wood fires. The trouble with eelgrass is, as was said before, that it will not rot in the soil. It must be coerced in some way in order to make its fertilizing constituents available for crops. It might be burned, for example, to ashes in order to get the potash and phosphoric acid: or, much better, the organic matter may be disorganized by composting the grass with lime or with rockweed. That is to say, the eelgrass may either be thrown into heaps, with layers of lime interpolated, in order to reduce the resisting tissue to a manageable form, or it may be built into a heap, layer by layer, with fresh rockweed or sea manure, and so subjected to destructive fermentation.

It is quite impracticable to form a close estimate of the total quantity of aquatic plants used for fertilizer in this country. The latest returns of the United States Fish Commission show an output on the New England coast of 75,000 tons, worth about \$1 per ton, but these figures probably do not show the total production. According to the Rhode Island census of 1885, \$65,044 worth of seaweeds were used in that State alone during the census year, compared with a total of \$164,133 worth of "commercial" fertilizers. This represents only a small percentage of the total quantity obtainable, it being possible to collect a thousand or more tons to the mile of that coast. The growth of the plants is rapid, and rocks scraped bare may be covered with kelp 5 or 6 feet long the following year.

WEIGHING SEAL PELTS AT ST. JOHNS, NEWFOUNDLAND.

UTILIZATION OF THE SKINS OF AQUATIC ANIMALS.

By CHARLES H. STEVENSON.

PREFATORY NOTE.

The utilization of the skins of animals is coexistent with the development of human activities. To the primeval man they were invaluable. They clothed and protected his body from the weather; they supplied him with tents, with boats, with thongs for the chase, and with innumerable articles requiring the use of firm membranous structure. The development of the textile industries, however, greatly reduced their relative importance, and spinning and weaving now to a very large extent supply the articles formerly made from the skins of animals. While by no means so important to man as formerly, numerous uses yet exist for these products and create a demand for them approximately equal to the present resources.

The skins of most mammals are covered to a greater or less extent with hair, which serves to protect the body against external influences, especially that of low temperature. In addition to the hair, and coexistent with it, many animals, particularly those of cold latitudes, have fine, soft underhair, termed fur. When the fur is sufficiently thick and soft, its value, left on the skin, exceeds that of any leather which can be made from the membranous tissue alone. This gives two classes of skins, (1) those deriving their value from the covering of fine underhair, which are used as furs, and (2) those dressed as leather without the hair. The present paper is, therefore, naturally divisible into two parts, the first relating to aquatic furs and the second to aquatic leathers.

While the writer desires to acknowledge his indebtedness to all persons who have rendered assistance in the collection of material for this paper, yet the number is so large that to cite each one individually would be to list the principal manufacturers and merchants handling furs and fancy leathers in America and many in Great Britain, each of whom has been uniformly obliging in furnishing all information asked for. However, it is desired especially to refer to the courtesy of Mr. Alfred Frazer, Mr. Max Bowsky, Mr. Adolph Bowsky, Mr. Samuel Williams, Mr. Joseph Ullman, Mr. Belden, and Mr. Robert Badcock, of New York City. To Messrs. John Russitz & Co. and to Messrs. Revillon Frères, of New York City, we are indebted for the loan of furs for photographing purposes, and to Messrs. Tiffany & Co., of New York, for photographs of several aquatic skins.

AQUATIC FURS.

GENERAL REVIEW.

Exclusive of the great variety of rabbit, squirrel, and opossum skins produced in all parts of the globe, a large portion of the world's product of furs is obtained from aquatic animals. Indeed, the trade in fancy furs is made up very largely of the skins" of those animals.

An examination of the sales made in 1901 by the largest furbrokerage house in the world shows that the aquatic furs constituted 49 per cent in number and 54 per cent in value of all peltries handled. Of the furs produced in the United States, fully 75 per cent in value are yielded by aquatic animals. Formerly the proportion was much greater, but is reduced by a decrease in product of beaver, fur-seal, otter, and sen-otter, and the large increase in quantity of rabbit, opossum, raccoon, etc., which have multiplied with the settlement of the country.

The principal fur-producers among the aquatic animals are the furseal, mink, muskrat, beaver, otter, sea-otter, and nutria. The greatest value is placed on the sea-otter, the choicest skins selling for upward of \$1,200; the number of sea-otters obtained annually, however, has been reduced to about 600. This fur has never been fashionable in western Europe or the United States; the market for it exists in China and Russia, those countries using probably 85 per cent of all the skins secured since its introduction into commerce in the seventeenth century. For two hundred years previous to 1800, beaver was by far the most important item in the fur trade as regards the total value of the product. The increasing searcity of that animal, however, and the adoption of substitutes have greatly depreciated its prominence.

During the last thirty years, fur-seal skins have outranked all others in commercial importance, being the fashionable material in Europe and America for ladies' garments for use in the cold weather. Since 1890, the product of fur-seal has greatly decreased, especially in the territory of the United States, and at the present time the yield of mink in this country is more valuable. The latter is probably the most durable of all furs, but the demand for it is very irregular, the market sales not exceeding 200,000 or 300,000 skins in one year and in a short while increasing to a million or more. Next to these in

a Among the furriers the term "skin" is used to designate the fur and the membranous tissue combined, while "pelt" is restricted to the membranous or coriaceous portion of the animal's coat, which is contrary to the general usage. The term "fur" in a general sense refers to the soft underhair of the fur-bearing animals. The skins of these animals, when removed from the body and cured, are called peltry. When the membrane is converted into a form of leather by a process called "dressing." the skin obtains the name of fur in a restricted sense. The term fur is also applied in a still more restricted sense to the underhair cut from the skin and presented in the form of delicate filaments for felting purposes, but this is more commonly known as hatters' fur.

aggregate value, but of far less value individually, is the muskrat, of which about 5,000,000 are slaughtered annually. The nutria or coypu is a small, beaver-like animal found in large numbers in South America, and about 2,000,000 are taken annually. Many thousands of beaver and otter skins are obtained each season, and each of these forms an important item in the fur trade.

The following summary, condensed from the table appearing on page 287, shows approximately the total quantity of aquatic furs produced throughout the world in 1900:

| Designation. | Number of skins. | Total area. |
|--|--|--|
| Beaver Fur-scal. Mink. Muskrat. Nutria Ottor Sea-otter | $\begin{array}{r} 66,000\\ 95,485\\ 728,000\\ 5,285,000\\ 1,950,000\\ 33,640\\ 590\end{array}$ | Square fect. 264,000 535,700 400,000 3,488,100 1,891,500 93,183 4,595 |
| Total | | 6, 677, 078 |

Classified statement of the world's product of aquatic furs in 1900.

The foregoing table shows the great importance of the muskrat in the trade, the aggregate area of the skins yielded annually by that animal being as great as that of all other aquatic furs combined, and more than six times as great as that of the fur-seal. Indeed, the aggregate area of the muskrat skins secured annually in the United States is approximately twenty times as large as that of the fur-seal product. The nutria ranks second in total area, but about 30 per cent of those skins are used by manufacturers of hats. Far below these two comes the fur-seal with 535,700 square feet, or scarcely 8 per cent of the total area of aquatic furs produced. Lower yet, in this particular, rank the mink, beaver, and otter; while of sea-otter fur only \pm ,595 square feet were produced in 1900, or less than one-fifteenth of 1 per cent of the total area of aquatic furs yielded during that year.

There are many industries more or less directly associated with the fur trade. Omitting the manufacturers of traps, guns, boats, vessels, and other apparatus and equipment, the men principally interested are the many hunters, trappers, and the like engaged in securing the pelts. Then come large numbers of men who collect the furs, transport them to the trade centers, effect their sale, and distribute them to the places of consumption. Next are the fur-dressers, who prepare the raw, greasy pelts and make them suitable for manufacture. The fur-manufacturers employ a very large number of skilled workmen, including assorters, cutters, nailers, sewers, etc. In addition to these are the wholesale fur-dealers and the numerous retail merchants. It is estimated that the number of persons employed in the United States in the various branches of the fur trade approximates 15,000.

THE FUR SUPPLIES AND MARKETS.

From the Middle Ages to 1600, Russia was the great source of furs for the world. Many skins were obtained in other parts of Europe and Asia, but even in the aggregate the quantity was relatively small. The discovery of the resources of North America changed the current of the trade, this continent soon becoming the great fur territory; and during the last three hundred years the United States and Canada have been the principal fur-producing countries.

The prominence of the United States in the product of aquatic furs is especially notable, the value of the raw skins produced in 1900 being \$2,302,100, whereas the total for all other countries was \$2,960,610. This country yielded 80 per cent of the muskrat, 70 per cent of the mink, 56 per cent of the sea-otter, 35 per cent of the otter, 30 per cent of fur-seal, and 12 per cent of the beaver produced throughout the world.

The importance of the Dominion of Canada as a producer of aquatic furs is very much less than that of the United States. Indeed, excluding the take of the fur-seal in the pelagic fishery, the total value of aquatic furs secured in that country in 1900 amounted to less than \$1,000,000, only 40 per cent as much as in the United States. The aquatic furs obtained in the limits of Canada are beaver, mink, otter, and muskrat. The fur-seal fishery as a Canadian enterprise is of comparatively recent origin, dating from about 1880, and the animals are caught in the Pacific Ocean and Bering Sea at a great distance from Canadian territory.

Russia, especially that portion bordering the Pacific Ocean, at one time yielded the great bulk of aquatic as well as of other furs on the market, the product of sea-otter and fur-seal being particularly large. Owing to the cession of Alaska to the United States and the increasing scarcity of furs on the Siberian coasts, the importance of Russia in this particular is now greatly reduced. South America yields only two aquatic furs of consequence, viz, nutria and fur-seal. Several species of otter occur there, but they are of little value and few are taken. Japan yields some fur-seal and sea-otter skins. From Europe, Africa, Australia, and the southern coast of Asia the product of aquatic furs is of very little importance.

The annual yield of aquatic furs fluctuates greatly, and an estimate of the collection is far from reliable, except for the particular year to which it relates. When furs of a special variety are fashionable, hunting becomes active; as a result the quantity placed on the market lowers the price and the hunt declines, giving the animals another opportunity to increase in numbers. While there are no means of learning the exact quantity collected during any one year, in view of the fact that the great bulk are handled at the London auction sales it is possible to form a very close estimate of the total product.

With the assistance of several of the principal fur-houses of the world, including the Hudson's Bay Company, Mr. Alexander Fraser,

TUBBING, COMBING, AND REVERSING FURS.

FLE3HING MINK SKINS.

and Mr. Joseph Ullman, the following estimate is made of the number of aquatic skins produced in the United States and in all other countries combined during the year 1900, and their value in the wholesale trade:

| Designation. | United States. | | All other countries. | | Total. | |
|---------------------------|----------------------|---------------------|-----------------------------------|-------------------------------|-----------------------------------|---------------------------------|
| | Number of skins. | Value. | Number of skins. | Value. | Number of skins. | Value. |
| Beaver. Fur-seal. | 24,000 | \$39,860 660,000 | 58,000 71,485 | \$301,200 1,471,000 | 66,000 95,485 | \$341,060 2,131,000 |
| Mink Muskrat Nutria | 578,000 4,035,000 | 810,000 565,000 | 150,000 1,250,000 1,950,000 | 330,000 138,000 444,000 | 728,000 5,285,000 1,950,000 | 1,140,000 703,000 444,000 |
| Otter Sea-otter | 14,600 . 330 | 93, 260 133, 980 | 19,040 260 | 170,850 105,560 | 33, 640 590 | 264, 110 -239, 540 |
| Total value | | 2,302,100 | | 2,960,610 | | 5, 262, 710 |

Classified statement of the product of aquatic furs in 1900.

During the summer months the skins of most of the fur-bearing animals are practically worthless, the thickest and finest part of the fur being shed as warm weather approaches, growing again in the fall to protect the animal in winter. This deterioration furnishes great protection to the animals, their value in the summer pelage being so small as to not warrant their capture. Furs in best condition are designated "prime," and this state is indicated by the color of the pelt. That of a prime skin is generally very light and clear, but as warm weather approaches it becomes bluish and dark. Most aquatic furs in the United States become prime about the middle of November and remain so until March, but beaver and muskrat are not thoroughly prime until late in December and are good until the last of April, while the fur of the otter may be prime as late as the end of May. There are two prominent exceptions to the general rule of taking fur-bearers during cold weather only, viz, the sea-otter and the fur-seal. The fur of the former is prime throughout the year, and the latter is taken principally during the summer for convenience of capture.

In addition to the protection afforded by the poor condition of the pelage, many governments have interdicted the capture of certain furbearing animals from a definite date in the spring to a fixed date in the autumn. There is no uniformity in these regulations in the different States and frequently in different counties in the same State.

None of the aquatic fur-bearers is utilized to any extent for food, though the meat of the muskrat is used by some persons; nor are these animals valuable except for the furs, which constitute the principal, and in most instances the sole, object of their capture.

With the exception of the taking of the fur-seals on the rookeries, practically all the aquatic furs are obtained by a resort to skill and stratagem. Many muskrat, mink, and otter are obtained by farmers and villagers. During cold weather, when furs are prime, comparatively little work is done in rural sections, and thousands of men and

boys find profit and sport in matching their skill and cunning against those of the wary animals. The greater portion of the peltries, however, are secured by professional trappers and hunters, who devote themselves entirely to that work during the season.

In taking or killing fur-bearing animals the use of guns or spears is avoided whenever possible, as they injure the skin by making holes in the pelt. Shooting is especially wasteful in taking aquatic animals, since a large percentage of these sink when shot, and are thus lost; furthermore, the shot cut paths in the fur, sometimes several inches in length. Neither should they be taken by poisoning, as this spoils the skin, the poison spreading through the body of the animal and injuring the texture and gloss of the fur, greatly depreciating its value.

The best method of taking these animals is by clubbing them on the head whenever that is practicable, as in the case of fur-seals, or by means of steel traps in case of the smaller and wilder animals.

Previous to 1670 the fur trade was centered in Leipsic, Amsterdam, Paris, and Vienna, the markets of Leipsic being the most important. Comparatively few choice furs were handled in London or in any market center other than those named. But shortly after the inauguration of its business in 1670, the Hudson's Bay Company began disposing of its receipts of peltries at public auction in London. Within a few years the continental markets relinquished the bulk of their trade to the new insular rival, and from that time to the present London has been preeminent as the greatest fur center of the world. The series of sales occurring at stated intervals at the various warehouses in that city dispose of the great bulk of the world's product of fancy furs. The American merchant, for instance, goes to London to buy the pelts that were obtained and shipped even from the vicinity of his own home. The reason for this is not difficult to discover. The principal fur company of the world has its headquarters in that city: the fur trade is better understood there at present than in any other large commercial center, and the importance of its being centralized makes it comparatively easy to hold when once secured; also the business ranks well among the London bankers, and they advance money on consignments of furs, and the consignor can negotiate his bill of lading on the receipt of his bales of peltries.

Although none compares in extent with that of London, there are several other markets which assist in the general work of distribution. Most celebrated among these are the fairs at Leipsic, which have existed over five hundred years. The Easter fair is the most important. This commences a week after Easter and lasts about two or three weeks. Large quantities of American peltries, especially muskrat and mink, are disposed of there. Furs are marketed in much smaller quantities at two other fairs held in Leipsic, one at Michaelmas and the other at New Year. New York City is the great fur center in this country, not only for accumulating the raw goods but for dressing, dyeing, and manufacturing as well. Indeed, New York leads the world as a consumer of furs, the sales to individuals there exceeding that of any other city in the world. Many firms long established, with large capital and of international reputation, carry on the business. At present there are 93 fur houses in New York, many of which have branch establishments and resident partners in London, Paris, Leipsic, Shanghai, etc. In view of the fact that a very large percentage of the furs of the world originate on the North American continent, and that the rank of the United States as a fur-consuming country is constantly increasing, it seems not improbable that the enterprise of New York may result in that city securing a large portion of the wholesale trade which now centers in London.

In addition to these large centers, the work of fur distribution is carried on by traders and merchants in almost every section of the world, scarcely any large town being without its quota of fur stores of greater or less importance, according to the climate and the wealth of the inhabitants.

In the markets, the skins of each variety are graded according to their size and the condition of the fur, the number of grades or classes depending on the importance of the particular variety, the cheaper peltries requiring fewer grades than those of greater value. For the purpose of showing the comparative value of the different aquatic furs, the following summary is presented, indicating for dressed prime skins of each variety the average area in square inches, the average value in the wholesale markets of the United States in 1901, and the resulting value per square foot of area.^{*a*}

| Designation. | Area. | Value per - skin. | Valu squar | |
|-------------------|----------|----------------------|---------------|---------|
| | Sa. inch | 28. | 1 | |
| Sea-otter, dark | 1.2 | \$600.00 | | \$67.24 |
| brown | 1.2 | 200.00 | | 22.41 |
| Fur-seal, Alaska. | | 45,00 | | 6.89 |
| Copper | | 34.00 | 0 | 5.58 |
| Mink, Canadian | | 2.60 | | 5.1 |
| Minnesota | | 2.73 | | 4.38 |
| Pacific. | | 1.80 | | 3.12 |
| Otter, Canadian | 4 | 0 10.33 | 1 | 3.27 |
| Pacific | | 18 7.90 | | 2.5 |
| Southern | | | | 2.08 |
| Beaver, Canadian | 6 | 7, 55 | | 1.71 |
| Pacific | | 7.05 | | 1.56 |
| Southern. | | 5, 80 | | 1.49 |
| Nutria | | | | . 5: |
| Muskrat, dark | | .34 | | . 49 |
| light | | | | . 25 |

Comparative statement of the average area, value, and value per square foot of the different aquatic furs in the United States markets in 1901.

^aIt will be observed in comparing this summary with the tables on pages 285 and 287 that the average areas and values used here are in excess of those in the tables. The explanation of this seeming discrepancy is that the figures in those tables refer to all classes of skins in a raw state, including the smallest and cheapest, whereas the present figures are for dressed skins and only those of prime grade.

F. C. 1902-19

FUR DRESSING AND DYEING.

The appearance of aquatic furs as they come from the hunters and trappers is quite different from that which they present when ready to be cut into garments. They are more or less greasy and dirty and require thorough cleansing. The pelt or membrane must be converted into a form of leather and made soft and pliable, and in some varieties it must be reduced in thickness. The overhair of many skins is quite undesirable and must be removed, this being the case with the furseal, beaver, nutria, and cheap grades of otter. The overhair is not removed from all varieties, however; for in some it constitutes the principal attraction, as in the sea-otter, mink, muskrat, and choice grades of otter. The fur-seal alone among the aquatics is usually dyed, but many cheap grades of other varieties are also dyed for the purpose of imitating more valuable ones.

In the dressing of aquatic furs there are no especially valuable trade secrets; but, as in nearly every other industry, some establishments have methods of treatment which they consider superior to those used by others and which they desire to keep from general use. As a rule, however, these secret processes are for the purpose of substitution or imitation, and have little standing among the most successful furdressers. In the best establishments the excellent results are due to conscientious application of well-known methods, without stint either in amount of labor or quality of material.

The fur-dressers of the United States are preeminent in the preparation of otter, mink, and beaver, while those of Germany rank well in dressing beaver and muskrat furs. The English have excelled for forty years in the dressing and dyeing of fur-seal skins and have prepared the great bulk of those on the market, but the Americans and French now prepare them equally well. The Chinese fur-dressers are the most ancient and among the best in the world. They dress seaotter skins remarkably well and secure wonderful effects in matching furs of all kinds.

The principal fur-dressing establishments in this country are located in New York City, where the great bulk of the skins are prepared. Smaller establishments exist in Chicago, St. Paul. Newark, and Phil adelphia. In Europe the fur-dressing is centered at Leipsic, Weissenfels, and Lindenau, Germany; London, England; Paris and Lyons, France; and Moscow and St. Petersburg, Russia.

When received at the fur-dressers, peltries are usually hard, greasy, and dirty. If very greasy, as in the case of mink skins, the surplus grease is scraped or beamed off. The skins are soaked in water over night for softening and opening the texture preparatory to the unhairing and leathering processes. Salt water is generally used for soaking, especially during warm weather, as its tendency to loosen

SKIVING BEAVER SKINS.

BEAMING AND PLUCKING BEAVER SKINS.

UTILIZATION OF THE SKINS OF AQUATIC ANIMALS. 291

the hair is less than that of fresh water. Heavy pelts, as of beaver, otter, etc., are beamed the following day for the purpose of breaking up the texture of the membrane and softening it. The beam on which the skins are successively placed for this purpose is made of some hard wood, as locust, boxwood, etc.; it is about 40 inches long and 8 or 10 inches wide, and is placed at an incline of about 45 degrees. The breaker is a dull scraping knife, with a handle at each end like a carpenter's draw knife, and is always operated in a downward direction. After beaming, the pelts are washed in warm soap water until perfectly clean and then they are freed of moisture.

If the overhairs are to be removed, that process is next in order, except in the dressing of muskrat skins, when it is usually postponed until after the dressing. In preparing for plucking, the hair side is dried and warmed by artificial heat, the membrane being kept moist in the meantime. Each skin is placed flesh side down on a flat, hardwood beam, similar to that used in breaking except that it is covered with thick, elastic leather. Chalk is first sprinkled over the hair, and then, using a knife similar to that employed in breaking, a workman rubs or works most of the overhairs out of the membrane. Those not removed in this manner are subsequently plucked out with a dull knife of soft metal. With this knife in his right hand and his thumb protected with a rubber cot about 4 inches in length, the picker grasps the hairs between the edge of the knife and his protected thumb, and with a quick, jerking motion pulls them out, going over the entire pelt in this manner. The fur-seal is guite difficult to unhair, and the process is more complicated, as may be seen from the description on page 305.

After plucking, the heavy pelted skins—as beaver and otter—are placed successively on a beam and shaved to a thin, even surface with a skiving knife. The blade of this knife is a straight piece of steel sharpened to a keen edge, which is then turned at right angles to the plane of the knife by means of a peculiar flat steel. This blade is fastened in a tool having two wooden handles differently attached, one running parallel to or in direct continuation of the blade, and the other placed at right angles thereto. Each skin is placed, fur down, on the beam, and by pushing the skiving knife downward and forward from his body, the workman scrapes the pelt perfectly clean and shaves off some of the membrane for the purpose of rendering it less bulky and more pliable.

The skins are now ready for leathering. The pelt side is dampened over night with cold salt water, and the following day butter or other animal fat is rubbed on the membrane. In dressing very fat or oily pelts, as those of mink, the greasing is omitted.

The pelts are then tubbed. This is probably the most noticeable operation in the fur-dressing establishment. Tubs or half hogsheads, slightly inclined backward from the floor, are located in a row along one side of the room. A number of skins are placed in each one, usually with a small quantity of sawdust. A workman with bared feet enters the tub, with a heavy cloth or piece of bagging tied about his waist and to the chimb of the tub to prevent the sawdust from flying out and to retain the heat. By treading and twisting movements he works the skin over and over for two or three hours or more until the pelt is thoroughly softened or leathered. It is a strange and interesting sight to see 10 or 12 men working in an equal number of tubs placed in a row, each person monotonously treading and swaying from side to side in solemn manner.

Tubbing is gradually giving way in a greater or less extent to the "tramping machine," whenever anything less than the very best work will suffice. This machine is adapted from the French apparatus for fulling wool stock. It consists of two wooden hammens, which are moved alternately back and forth or up and down in a suitable receptacle, agitating the skins slowly and constantly, turning them over and over each other, and developing by friction the necessary heat, thus rendering the pelts soft and pliable. This process is far more economical than tubbing, costing only 10 or 20 per cent as much. The result, however, is not always so satisfactory, and for the choicest skins tubbing is yet generally used.

At this stage of the dressing process comes the fleshing or skiving, the former being applied to small skins and the latter to large ones. Fleshing consists in removing all particles of flesh and fat by means of a fleshing knife, formed with a broad blade having a sharp edge, fastened in an upright position on a bench. The workman sits astraddle the bench immediately behind the knife, with the edge turned from him, and proceeds to flesh each pelt by grasping it with both hands and drawing it repeatedly across the sharp edge of the knife, cutting off the superfluous flesh. Only small skins, such as mink and muskrat, are fleshed in this manner. Large skins, as those of beaver, otter, etc., are shaved on a beam with a skiving knife, in much the same manner as before the leathering process, except that the operation is performed much more carefully.

After fleshing or skiving, the skins are usually put through the tubs or tramping machines a second time, and on removal therefrom are cleaned of grease. In this operation two forms of revolving drums are used, one known as the cleaning drum and the other as the beating drum. The purpose of the former is to extract the grease by means of dry sawdust, and of the latter to remove the sawdust. The drums are usually about 4 feet wide and 6 or 8 feet in diameter, but the size is entirely a matter of convenience and desired capacity.

The cleaning drum is made of wood, and upon its interior circumference are four or five wooden shelves about 6 inches wide and at suitable distances apart. Instead of these shelves some drums are provided with rows of wooden pins or pegs 6 or 8 inches in length and similarly situated. Sometimes each cleaning drum is inclosed in a wooden

UTILIZATION OF THE SKINS OF AQUATIC ANIMALS. 293

closet, which is heated by steam pipes or a charcoal fire. A number of skins, with a quantity of fine, dry, hard-wood sawdust, are placed in each drum. The latter is revolved steadily, making about 20 revolutions per minute, and within three or four hours the dry sawdust absorbs the grease, leaving the fur clean and soft but filled with sawdust.

The beating drum, also sometimes inclosed in a closet, has wooden ends, and the side or circumference of wire gauze, with meshes about one-fourth inch square. Along the interior circumference are wiregauze shelves about 10 inches wide, which catch the pelts at the bottom of the revolving drum and carry them nearly to the top, when they slide off and fall against the wire gauze covering the circumference of the drum. In this manner the pelts are cleaned of every particle of sawdust. Many of the larger pelts are beaten with rattans for the same purpose.

After removing the sawdust and straightening the fur with a steel comb, the dressing process is at an end. This general process would suffice fairly well for all varieties of aquatic furs, but it is modified to suit the characteristics of the different sorts. The special methods applicable to each variety are described at length in appropriate chapters.

Except in case of very cheap skins, the expense of dressing furs represents only a small percentage of their value. The following tabular statement shows the average charges that prevail in New York City for dressing skins in quantities for the trade:

Statement of average charges prevailing in New York City for dressing aquatic furs.

| Species. | Dressing. | Dressing and plucking |
|-------------|-----------|--------------------------|
| Beaver | | \$0.6 |
| Fur-seal a | | 3.00 |
| Mink: Cased | . 15 | |
| Open | . 14 | |
| Mink tails | . 03 | |
| Muskrat | | . 08 |
| Nutria | | |
| Otter | . 50 | . 65 |
| Sea-otter | 2.00 | |
| Sea-otter | 2.00 | ••••• |

a Dressing, plucking, and dyeing, \$5.

With the exception of the fur-seal, the choicest furs of any particular species are rarely dyed. Indeed, their degree of excellence is determined by the nearness of their approach in the natural color to the most desirable shade for that species. So important is this that a skin of the proper tint may be worth three or four times as much as one whose texture is equally fine but lacking just the right shade. For instance, the present average value of prime dark sea-otter skins is about \$600 each, whereas the average price of prime brown skins is only \$200. In case of mink, otter, and other choice species the difference is as great in proportion. In order to obtain those shades which taste and fashion have determined to be the most desirable, much of the aquatic fur is dyed; either the ends of the fur and hair are merely tinted, or the color of the entire skin may be changed. The object of tinting or blending is to make all parts of the fur used in a garment of the same color, to make an inferior grade of fur like that of a superior, or to cause the fur of one animal to resemble that of another. Certain furs so closely resemble choicer ones in every particular except color that when dyed to a similar hue they are almost indistinguishable to the casual observer.

While dyeing may be a cheap and ready process in the treatment of low-priced furs, it is an art when applied to choice skins. Its perfection consists in the exact imitation of the proper color and tint, with the preservation of the glossiness of the fur and its natural firmness and pliability, and, finally, in the durability of the dye. In case of the fur-seal, fashion has decided that the color shall be changed to a lustrous blackish-brown, an original color resembling nothing whatever in the animal kingdom.

Some skins of beaver, otter, etc., are "silvered" by passing lightly over them a solution of sulphuric acid, and also some are made a golden yellow by means of peroxide of hydrogen. Dyed furs are generally not so durable as those left in the natural state, the artificial color fading and the garment sooner presenting an old and worn appearance.

The dycing of furs is of great antiquity, but its principal development, in America and Europe at least, has been within the last forty years. Experiments on the part of conscientious and able chemists have resulted in greatly improving the permanency of the dyes and lessening their injurious effects. The methods are constantly undergoing changes and many improvements are introduced from time to time. The composition of the new dyes and the methods of applying them are carefully guarded from general knowledge. One frequently runs across published directions for compounding the dyes and methods of applying them, but usually these descriptions are totally valueless, the methods described being either superseded by better ones or lacking in certain essential ingredients.

The number of successful dyers in the world is very small; their prosperity is dependent as much upon the elimination of competition as on the excellence of their work, consequently they are not proclaiming from the housetops the composition of their dyes, frequently the results of long and costly experiments.

In the separate chapters devoted to each variety of furs certain general methods of dycing those particular skins will be described, but the writer is unable to promise the formulæ and details of the newest and most successful dyes in every instance.

AQUATIC FURS USED BY HATTERS.

During the seventeenth and eighteenth centuries an important if not the principal use of aquatic furs in Europe was in making fashionable hats, commonly called beaver hats, beaver fur being the chief material in their make-up. The general adoption of the silk hat about sixty years ago resulted in greatly reducing the quantity of aquatic furs used by hatters, but those manufacturers are yet large consumers of these articles for the production of fine grades of soft hats.

The principal felting furs among the aquatics are nutria, muskrat, beaver, fur-seal, otter, and mink, named in the order of the extent to which they are now used. Rabbit, cony, and have furs are used far more extensively than all the foregoing combined, owing to their cheapness, but are less desirable than most varieties of aquatic furs. Hatters' furs are both cut and blown, the former being taken from the whole skins, and the latter from small pieces, clippings, roundings, and other waste obtained in cutting skins for sewing into garments.

The choicest felting fur is that of the beaver; but its high cost limits its use in hat-making. A felt hat of average size and weight made of fur cut from choice beaver pelts could not be made for less than \$500 per dozen, and no demand exists for such expensive goods. But manufacturers receive a quantity of beaver cut from damaged skins of little value as dressed fur and also considerable blown from clippings and the waste from cutting skins into garments. The choicest beaver fur for hatters' purposes is obtained from the cheeks of the animal, with that from the belly, the back, and sides, following in the order named.

Beaver clippings sell for about \$1 to \$1.25 per pound, and the fur, when blown free from hair and impurities, sells for \$8 or \$10 per pound. Cut beaver has been sold as high as \$224 per pound by brokers yet in the business. The quantity of beaver fur used by hat-manufacturers throughout the world averages about 6,000 pounds annually. It is made into very light soft hats, which sell wholesale at about \$80 or \$90 per dozen. These are very durable, and if occasionally cleaned or dyed may be worn almost indefinitely. A small demand still exists for the old fashioned beaver-napped hats, shaped somewhat like the present style of silk hat, being the fashionable headgear for the guards on drags and coaches, and to a small extent for ladies' riding hats.

The next highest grade of fur used by hat-manufacturers is nutria, which is the standard choice fur for making into soft felt hats. It is estimated that about one-third of the total product of nutria skins are cut for hatters' use, and in addition the hat-manufacturers receive large quantities of blown fur from manufacturers' clippings. Nutria is very nearly as desirable as beaver for felting, selling at present for about 80 per cent of the value of the latter, whereas in the dressed-fur trade it is worth only 30 per cent as much as an equal area of beaver fur. During the past twenty-five years the average value of cut and blown nutria fur has ranged between \$2.25 and \$7.50 per pound. In

1877 it was \$5.50, and gradually decreased to \$2.25 in 1886; it increased to \$7.50 in 1897, and in 1900 it averaged \$6.50 per pound. Single sales have been made as high as \$14 per pound. The total product of nutria fur used in hat-manufacturing in 1900 is estimated at 80,000 pounds, valued at \$520,000. It is claimed that a single manufacturer in Philadelphia has at times over a million nutria skins in warehouse.

Otter ranks next in grade among felting furs, but only a small quantity of this kind is used, and that is obtained from fur-cutters' waste. The clippings and waste sell for about 45 cents per pound, and the cut and blown fur for about \$3.50 per pound. The quantity used by hat-manufacturers annually probably approximates 700 pounds.

Muskrat fur is used extensively in hat-making, the whole skin as well as cutters' waste being utilized. Like beaver fur, it is assorted into three grades—backs, sides, and bellies—on account of difference in color and texture. The belly fur is the choicest and is used for making light or pearl hats. During the last 25 years the price has ranged from \$1.80 to \$3.25 per pound, averaging about \$2. In 1876 it was \$2.25, from which it varied little till 1890, when it began to increase, reaching \$3.25 in 1892, and since then it has steadily decreased to the present price, \$1.80 per pound. The cutters' waste sells for 35 to 40 cents per pound and the blown fur for \$1.30 to \$2 per pound. The standard mixed grade of blown muskrat fur usually sells for 30 or 40 cents less per pound than the belly fur, while dyed muskrat sells usually for onethird the price of cut belly, or about 60 cents per pound.

A small quantity of mink fur is used by the hat-manufacturers, the amount not exceeding 1,500 pounds annually, obtained entirely from cutters' waste, no whole skins whatever being used for this purpose. Mink fur is rather poor for felting, as may be inferred from the price at which it sells, the clippings fetching about 15 cents and the blown fur about \$1.10 per pound, or only one-sixth the price of beaver.

The cheapest aquatic fur-received by the hatters is that of the furseal, of which probably 5,000 pounds are used annually. This is obtained almost exclusively from cutters' waste of dyed clippings, and when cut and blown sells for about 75 cents per pound.

The preparation of all of these furs for felting purposes is practically the same in each case. Preparatory to cutting them from the whole skins, the pelts are scoured thoroughly with soap water to remove the grease and other impurities, then they are properly dried and plucked, each one of these several processes being performed in much the same manner as in the fur-dressing establishments, except that it is done with greater expedition and less care. The overhairs are of no value in felting, and are sold as stuffing in upholstery, for plasterers' use, etc. The plucked skins are next curroted, consisting in moistening the fur with a solution of quicksilver and nitric acid or chloride of mercury, and then spreading them out flat to dry. This is done either in the open air or in rooms heated by steam, according to the color desired. When dried in the open air the fur becomes whitish, and when dried by subjection to steam or other artificial heat it assumes a yellow, carrot-like hue. This explains the abbreviations W. C. (white carrot) and Y. C. (yellow carrot) always given in connection with the designation of each kind of felting fur. In the preparation of beaver and some other furs, the carroting is occasionally omitted, but this raw stock does not felt so readily and is usually mixed with properly carroted fur.

After drying, the carroted skins are brushed by holding each one for a few seconds against a revolving wheel studded with quills. This is for the purpose of removing all dust and to straighten the fur so that it may be readily cut from the skin. Originally the cutting was done by manual labor, a pair of shears being used, and later by means of an ingenious mechanism giving a chopping motion to a vertically mounted knife. At present a much better machine is used, which with great rapidity cuts the pelt from the fur in little narrow strips about one-sixteenth of an inch in width and equaling in length the width of the skin. These strips of coriaceous membrane fall into a receptacle and go to the waste heap or to the manufacturers of certain oleaginous compounds. An endless apron carries the fur forward without disarranging it or changing its natural formation, where it is properly assorted by experienced operators.

Each assortment consists of the fur from a particular part of the skin, the chief divisions being the back, the sides, and the belly. Fur cut from the back is the darkest in color; that from the sides is lighter, and somewhat lower in quality. The belly fur is nearly always the lightest in color. It varies in quality, however, being the finest of the principal grades when cut from the beaver, nutria, or muskrat skins, and the lowest when obtained from the skins of land animals, such as the conv and rabbit. Minor assortments consist of the fur cut from the tails of various animals and from the cheeks of the beaver, the latter being the choicest felting fur obtainable. Belly fur is used in making light-colored hats; that from other portions is available for the production of felt hats of every desirable color. All of these assorted furs are placed separately in paper bags, containing 5 pounds each in America and England and 11 kilograms each in France, in which they are stored or marketed.

The blown furs are those obtained from fur-cutters' waste, which every furrier establishment saves carefully. These pieces are assorted and sold to the cutters of hatters' furs at prices ranging from \$1.25 per pound for beaver to 15 cents per pound for mink clippings. The furcutter runs them through a chopping machine, where they are cut into minute pieces, and afterwards are repeatedly blown to separate the fur from the overhairs and pieces of skin. Blown fur is not usually carroted, and since it is short and is not readily assorted into various grades it sells for considerably less than cut fur.

THE SKINS OF FUR-SEALS.

DESCRIPTION OF THE SKINS.

There are two distinct groups of marine mammals commonly called seals. The members of one family, the *Otaridæ*, provide the fashionable fur, and are known generally as fur-seals; while the *Phocidæ* supply seal leather and oil, and are called seals or hair-seals.

The northern fur-seal pelts on the market are of three sorts, viz: Alaska skins, Copper skins or Copper Island skins, and Northwest Coast skins. Of the southern pelts the principal varieties are the Lobos, the South Shetland, the Cape Horn, and the Cape of Good Hope skins; but the present yield of these is quite small compared with that of the northern skins. These several classes of pelts are distinguishable from each other and sell at different prices. The Shetland Island skins are the choicest, but they are now very scarce and are rarely on the market. Of those obtainable in marketable quantities, the most valuable are the Alaska skins; next are the Copper skins; and the Lobos and Cape of Good Hope skins are of least value.

The pelage of the Alaskan fur-seal consists of a nearly uniform coating of dense, soft fur overtopped by coarse rigid hair of varying length. The coriaceous membrane is thin, pliable, and of light weight. The fur increases uniformly in thickness and fineness all over the body until the third or fourth year, when it is about three-eighths of an inch in length and is in its greatest perfection. After the fourth year it grows longer and thicker on the neck and shoulders and becomes thinner on the posterior parts, thus deteriorating in value. The hair overtopping the coating of fur is longest on the back of the neck, where in case of 4-year-old males it reaches a length of 2 inches or more; on the posterior parts it is shorter, and near the hind flippers it is usually less than an inch in length; on the limbs it is much shorter and less dense, and in some places quite absent. It is shed annually in August and September, new hair appearing as the old is cast. The process occupies about six weeks, and while in that condition the skins are known as "stagy," and are of inferior value owing to the amount of labor required in the process of dressing.

The Alaskan skins have constituted the greater part of those on the market since fur-seal has been fashionable in Europe and America. The Pribilof Islands, whence they are obtained, have probably yielded one-third of the total product of fur-seals of the last two centuries, and 80 per cent of those secured in the last seventy-five years. From the reports of the United States Treasury Department, it appears that from 1870 to 1900, inclusive, 1,837,563 marketable fur-seal skins have been shipped from the Pribilof Islands, and the revenue to the United States Treasury has amounted to \$7,812,036.

The fur of Copper skins, from the Commander Islands, is coarser and less dense than that of the Alaska skins, and commands a lower price in the markets, usually about 70 per cent of the price of the latter. The pelt is also less porous than that of the Alaskan skins, this being especially noticeable in the process of working them preparatory to leathering. It is far more difficult to unhair a Copper skin, as the membrane is harder and stiffer and the hair more brittle.

Since 1871 the Russian Government has leased the sealing rights on the Commander Islands under conditions similar to those in the Pribilof lease. Following this, the number of skins secured averaged between 35,000 and 40,000 for upward of twenty years, but during the last six years it has greatly decreased.

The skins from Robben Island, in Okhotsk Sea, were formerly classed separately from those obtained on the Commander Islands, and were regarded as inferior, owing to the greater difficulty in removing the hair and the lighter color of the fur. Improved methods of dressing and dyeing have lessened this difference, and within the last fifteen years they have been combined with those caught on Copper Island and included in the term "Copper skins."

The Northwest skins are obtained in the North Pacific Ocean and the adjacent seas, and are the product of the so-called pelagic fishery, which has occupied so much attention in diplomatic correspondence and in the public press during the last twelve years. Previous to 1881 the output of this fishery never exceeded 10,000 skins; then it increased until 1894, when the catch was 141,143 skins, and since then it has greatly decreased, the product in 1900 being 38,923. Notwithstanding the fact that the Northwest skins are from the same herd as the Alaska skins, they are of much less value, many of them being taken out of season, when the fur is poor and the pelt stagy. As a rule they are not so well cured as the skins taken on the islands, and have many raw spots, a result of their being salted in the foul air of the ship's hold under indifferent supervision. They are readily distinguishable from the Alaskan and Copper skins by the fact that they are all pierced by bullet, buckshot, or spear, furnishing another reason for diminished value.

The Lobos Island fur-seal, at present the most numerous of all the southern members of this family, is obtained principally from Lobos Island, at the mouth of the Rio de la Plata, which is owned and controlled by the Republic of Uruguay. It is of a greenish or yellowishbrown color, with sides of a darker brown, and the fur is comparatively long. The pelt is thin, rather spongy, and easy to work. Since 1825 the right to take seals on the island has been leased under a system of regulations resembling somewhat those in force on the Pribilof and Commander islands. The annual product is from 15,000 to 20,000. The total number of skins obtained since 1873 approximates 415,000, valued at \$4,000,000, a remarkable output for an island covering less than 1 square mile in area. The rookeries on this island are the only ones in all the southern seas which have been protected, and they

are also the only ones whose output has continued undiminished to the present time.

The general color of the South Shetland or Cape Horn fur-seal, according to Mr. Henry Poland, is light gray with a silvery hue: the neck and cheeks are whitish, and the sides and belly are of a rich brown. The fur is thick and heavy, and of a reddish or deep pink color. The habitat of this seal is the islands in the Antarctic Ocean. and it is more numerous on South Shetland Island than elsewhere. When in good condition this fur is the choicest on the market, its quality being much superior to that of the Alaskan seal, the high latitude and the rigor of the climate developing the fur into full perfection at the time when the seals seek those shores. During the seventies the skins of the South Shetland fur-seals sold for nearly twice the price of Alaskan skins, although, owing to the inferior quality of the leather, they are less durable. Since 1882 the receipts of Cape Horn skins have been small and irregular, ranging from 6,000 to less than 100 a year. The high prices of the pelts have resulted in the searching of every accessible beach and rock in the southern oceans and the removal of all fur-seals that could be secured, their only protection being the severe weather, which often makes it impossible to effect a landing on the rookeries.

The total number of fur-seal skins marketed since their introduction in the early part of the eighteenth century aggregates probably 13,000,000, of which 5,000,000 were secured from northern localities and the remaining 8,000,000 from the rookeries of the southern seas, the great bulk of the latter being marketed at Canton, China, a hundred years ago. At the present market price the total value of these pelts would approximate \$500,000,000, but owing to their cheapness in the early years, when the greater part of them were obtained, the actual returns have probably not exceeded a tenth of that amount.

In curing fur-seal skins preparatory to shipment it was formerly customary to dry them while held stretched upon the ground by the use of stakes and twine or by means of wooden pegs driven through the edges. It was often impossible to dry the skins thoroughly in the damp climate of Alaska; and even when artificial drying was resorted to, it was frequently difficult to prevent them from deteriorating while en route to market. The drying process also made it difficult to unhair the pelt in dressing. This led, about 1855, to the salting of the skins, which is now the general practice. However, a few are dried by the natives along the mainland and on the adjacent islands of Alaska, a thousand or more being marketed each year.

FUR-SEAL MARKETS.

Previous to 1855 fur-seal skins were in little demand in Europe or America. The fur was not fashionable and the skins were made into gloves and riding rugs, caps for cabmen and street peddlers, and even for the covering of trunks and boxes. Another use to which they were put when unusually cheap in the European market was to clip the fur from the skin and tan the latter for the general purpose of leather, while the cut fur was either discarded or manufactured into napping for "beaver hats." But few hats were made of this material after the adoption of silk felt.

About 1825 the unhairing and dyeing of fur-seal was introduced, and although the article was very poor compared with the choice product of the present time, it was a decided advance over the former methods of dressing. Between 1855 and 1870, through experiments on the part of Messrs. Oppenheim & Co., and of Messrs. Martin & Teichman, in London, and of Mr. George C. Treadwell, in Albany, the methods of dressing and dyeing fur-seal were greatly improved, resulting in an exquisitely soft and downy texture and rich dark-brown color, which was quickly adopted by the fashionable world for cloaks, jackets, muffs, trimmings, etc. So popular did the fur become that the demand quickly ran up from 10,000 skins in 1860 to 20,000 in 1865, to 150,000 during the seventies, and 200,000 during the eighties at greatly increased prices. The high prices resulted in excessive drains on the rookeries and unwise methods of slaughter at sea, so that the quantity of skins obtainable now is very much less than ten or fifteen years ago, only 95,485 being handled in 1900, and the price is much in excess of what it ever was before.

Previous to 1871 fur-seal pelts were comparatively cheap, the undressed Alaskan skin rarely selling for more than \$4 or \$5; but since that time the market price has greatly increased. In 1875 Alaskan skins averaged about \$13 each; in 1880, \$20; in 1885, owing to the large number received from the pelagic fishery, the price fell to about \$16 each, but in 1890 it increased to \$35, and in 1900 to \$40.

Since 1870 practically the entire world's product of fur-seal skins has been sold in London. Most of them are handled by Messrs. C. M. Lampson & Co., who receive consignments from the North American Commercial Company, the lessees of the right to take skins on the Pribilof Islands; from the Russian Sealskin Company, the lessees from the Russian Government of the rights on Commander Island and Robben Reef, and a large portion of the Northwest skins. Other prominent firms in London handling skins are the Hudson's Bay Company, Messrs. Boulcher, Mortimer & Co., the consignees for Lobos skins, and Messrs. Culverwell & Brooks, who receive many of the Northwest skins.

The skins are duly catalogued, and public-auction sales are held at stated times during the year, usually in March, October, and December, when all the leading furriers of Europe and America are represented, the number averaging about 50. Generally the entire stock on hand is sold at each occasion. The consignments of skins are assorted according to the size, the following grades being recognized:

| Name of class. | Age. | | |
|--|--|--|--|
| Wigs. Middlings and smalls Smalls. Large pups Middling pups. Small pups. Extra small pups. Extra stra small pups. Grey pups. | 4 years. 3 years. }2 years. 1 year. | | |

The following summary, compiled by Mr. Alfred Fraser, shows the total number of skins offered at the London auction sales during each year since 1872:

Statement of the number of each variety of fur-seal skins offered in London during a series of years ending in 1900.

| 1872 | $\begin{array}{c} 96,283\\101,248\\90,150\\99,634\\90,267\\75,410\\99,911\\100,036\\100,161\\99,921\end{array}$ | $\begin{array}{c} 7,182\\ 21,614\\ 30,349\\ 34,479\\ 33,298\\ 25,380\\ 19,000\\ 28,211\\ 38,885\end{array}$ | $16,312 \\931 \\8,843 \\3,575 \\4,097 \\1,945 \\3,610$ | 7,000 6,956 8,509 8,179 11,353 13,066 | $320 \\ 9,000 \\ 8,600 \\ 9,500 \\ 6,306$ | 127,097 139,749 146,451 155,369 |

a The 1896 skins were sold in December, 1896; no 1897 skins were sold until March, 1898.

Previous to 1820 no market existed for fur-seal skins in the United States, and practically all of those received from the Southern oceans were reshipped to China, either direct or by way of Europe. In 1822 Mr. Denison Williams, a cap-manufacturer of Albany, N. Y., introduced fur-seal caps to the trade. From a manuscript written by him, and now in the possession of Mr. Samuel Williams, we have extracted the following notes in regard to the development of this business:

In 1822 the first fur-seal came into our market. At that time no one knew a process of removing the hair from the fur, therefore we made them into caps with the hair on, which took well. The next season we used large quantities of fur-seal, and after a number of experiments succeeded in removing the hair, greatly increasing the value of the fur. Those skins were from the South Shetlands, then just discovered,

and were the finest ever found. The next season we prepared a lot of hair-seal caps which took well in the Southern markets. In the fall of the following season (1825) we succeeded in coloring both the fur-seal and the hair-seal skins, the first ever colored in this country, thus enhancing their value 100 per cent.

Mr. Williams was quite successful in the fur-seal cap business, establishing agencies in Boston, New Orleans, and Nova Scotia, and having made a net profit of \$60,000 in four years, retired in 1827. The business was continued by Mr. Williams's former associates, Messrs. Packer, Prentice & Co., who built up a large trade, their manufacture of various furs in 1831 amounting in value to half a million dollars. In 1833 Mr. George C. Treadwell, who in later years enjoyed so prominent a reputation in fur-seal dyeing, began dressing the skins, and in a few years others embarked in the business, making Albany the principal center in the United States for this industry. Fur-seal skins constituted a large item in the business, 20,000 being unhaired and dyed in a single year, nearly all of which were used in the manufacture of caps. Previous to 1835, most of the skins were dyed "London brown." In that year Mr. James Chase, of the Treadwell company, discovered how to give them a dark plum color, and afterwards deepened it to a deep sable hue.

The skins were obtained from the South Shetlands and other places in the vicinity of Cape Horn and from various places on the west coast of Africa. With the decrease in yield from these localities about 1840, the business at Albany began to wane, and finally fur-seal skins became so scarce that nearly every manufacturer ceased using them. Mr. Treadwell continued their use for caps and gloves, obtaining his supply of raw skins from the occasional lots received from the southern seas, supplemented by shipments of Pribilof skins from London.

The attention of Mr. Treadwell having been called to the growing demand in London for fur-seal sacques, he began dressing and dycing the skins for the trade in the United States. He did not produce the seal-black fashionable at the present time, but a reddish brown, which became known as seal-brown. This product gave excellent satisfaction, the dye retaining its bright color without fading. Meeting with sufficient demand for his output, he did not attempt to secure the black shade of color finally adopted by the London dyers in response to the demands of fashion.

Mr. Treadwell was the only fur-seal dresser in this country up to the year 1878, when Mr. J. D. Williams, of Brooklyn, the son of Mr. Denison Williams, referred to above, began dressing and dyeing the skins a dark brown, similar to the London color. At the present time, the sons of the late Mr. J. D. Williams, above noted, are the only fur-seal dressers and dyers in this country, although there are many who redye skins. The reason fur-seal skins are not dressed and dyed more extensively in the United States is not due to the high cost of labor here, for that is more than counterbalanced by the 20 per cent

import duty on the prepared skins; nor is it due to the lack of expert workmen. The principal reason is that the raw skins are sold in London and harmonious cooperation exists among the fur-brokers, fur-dressers, and bankers there, so that a first payment may be made on skins purchased in the fall, and most of the purchase money be withheld until the skins have been dressed, dycd, and made ready for manufacture six or eight months later.

In estimating the industrial value of the manufacture of fur-seal articles in the United States, seven of the principal furriers made affidavit in 1892, as follows:

The number of Alaska fur-seal skins that are imported annually into the United States, after dressing and dyeing in London, is, upon the basis of the importations during the past ten years and upon a catch of 100,000 skins at the Pribilof Islands, correctly estimated at 65,000 to 75,000. The value, before paying duty thereon to the United States, of each dressed and dyed fur-seal skin so imported, may be said to range between \$15 and \$50, with an average value during the past ten years of about \$25 per skin. The wages paid annually to people engaged in the manufacture and remodeling of seal-skin articles are, on an average, about \$7 a skin, or upon 70,000 skins, \$490,000. The profits made annually by merchants, wholesale furriers, and retail furriers amount to about \$30 a skin, or upon 70,000 skins \$2,100,000. The amount of silk consumed annually in the manufacture in the United States of 70,000 fur-seal skins into articles and in the repairing of these articles may be estimated at \$150,000 to \$200,000. All silk which is being so consumed at the present time is made in the United States. Working men and women are employed in the industry of manufacturing seal-skin articles in the United States as follows:

| Classification. | | Num- ber. | Wages J diem | per |
|---|---|---|---------------------------|--------------------------------|
| Fur-cutters (i. e., people who trim, repair, and prep skins) | shape on boards) le into final shape) on of guard hairs left by | $ \begin{array}{c} 1,200\\ 600\\ 1,500\\ 60\\ 3,360\\ \end{array} $ | \$3.50 to 2.00 1.50 | \$4.50 2.50 2.00 2.00 |

The fur-cutters represent skilled labor of a high order. No account is taken of porters, clerks, salesmen, etc., employed in the large establishments.^a

Owing to the smaller quantity of skins received on the market at the present time, the number of persons employed in manufacturing them into garments is much less than in 1892, probably not over 60 per cent as many. The total number of persons actively employed at present in various parts of the world in handling fur-seal skins from the live animals to the finished garments probably aggregates 4,000, and the total value of the product \$6,000,000 or \$8,000,000 annually.

METHODS OF DRESSING AND DYEING.

The present method of dressing fur-seal skins represents the highest development in the fur-dresser's art. The difference in appearance between a raw and a finished pelt of beaver, otter, or muskrat is comparatively small; but the raw fur-seal skins, as received at the furdresser's establishment in their dirty and unsightly condition, bear little resemblance to the finished product delivered to the garment manufacturers. The following account of the present methods of dressing these skins is based on information furnished by fur-dressers of New York and London, and especially by Mr. Samuel Williams and Mr. Max Bowsky, of New York City:

The moist skins are first freed of salt and then "blubbered," consisting in placing each skin, fur down, on an inclined wooden beam somewhat like a tanner's beam, and with a two-handled knife removing all particles of blubber, flesh, and other extraneous matter, care being taken that no cuts or uneven places are made in the pelt. These blubber scrapings are oleaginous and are usually handled by manufacturers of oils and greases. The skins are soaked in cold water over night and then washed in strong soap water, the amount of washing depending on the condition of the pelt, some pelts standing more than others, too much washing loosening the fur. Whale-oil soap was formerly considered necessary for this, but its use is now almost abandoned. After the washing, the skins are placed on a beam with the fur side up and the grease and water are removed by scraping or pressing with a beaming knife.

Then comes the depilation or unhairing, the most difficult and important single step in the process. In preparing for this, a slight difference of practice exists among the various dressers. Usually after the washing, as above noted, each skin is stretched and sewed with heavy cord to the rim of an iron hoop and suspended in dry atmosphere until thoroughly dry, usually requiring several days. Next they are soaked in cold water from one to three days, the length of time varying according to the condition of the skin and the temperature of the water. On removal the fur is dried and the skin made quite warm, doubled together, and sweated in a warm place from one to three hours or until the hair commences to start. In some establishments the drying of the skins on iron hoops is omitted entirely, and the fur is dried and the moist pelt warmed and sweated as above noted immediately after the washing process.

When the skins are in good working condition, the picker or unhairer bends several of them across boards by the side of a stove, and thus warms and dries the fur side, keeping the skin side moist in the meantime. Each skin while warm is successively placed on the unhairer's beam, pelt side down, and the hair removed by using a dull knife of soft metal, known as a picker's knife, the workman grasping the hair between the knife and his thumb, the latter being protected by a rubber cot. Extra force should not be used in case the hairs do not yield readily, for they are liable to break off; but the pelt should be again moistened and the fur side warmed. After a portion of the skin has been unhaired, it is necessary to warm another part of it at the

F. C. 1902-20

stove, keeping the pelt moist as before, and the operation is continued until the entire skin has been unhaired. In order that the hairs may be easily removed, it is necessary to heat the skin to the limit which it will stand without injury, and much experience is required to determine this limit. Many skins have been so injured in the unhairing that the fur loosens and readily comes out after a few weeks' wear.

For economy of time, a workman generally operates on three or four skins at the same time, unhairing one while the others are warming. The hairs must be pulled out and not broken off. Care is also taken to avoid removing the fur with the overhairs, and thus leaving bare spots on the pelt. Even after the above process stagy skins retain many short or second-growth hairs which reach a short distance above the fur. Many of these may be removed by the picker warming the skin and passing a dull beaming-knife rapidly over the fur. When the skins are very stagy they are sometimes unhaired in part from the skin side. The roots of the hair penetrate the membrane farther than those of the fur, and when the skin is pared down thin the hairs may be pulled out by grasping the base of the roots.

The skins are next stretched and nailed on boards and dried very hard, the drying continuing from two to five days to remove every particle of moisture. On removal they present the appearance of thin, uneven boards with little curls of brown fur on one side; these may be cracked or split by a person walking on them almost as readily as though of wood.

When opportunity presents, the dried skins are dampened on the pelt side with fresh or salt water and skived or shaved on a beam with a currier's knife to a thin, even surface. Salt is used in the water to prevent the fur from coming loose, but too much salt "cuts" the leather, and its use is not desirable except in hot weather. Some dressers postpone this shaving until after the fur has been dyed, but others are so annoyed by the grease coming out of the thick membrane and interfering with the dyeing of the fur that they thin the pelt at this stage of the process. The pelts are stretched and partly dried, being "worked" in the meantime to prevent their drying stiff and hard.

The pelt side is then covered with butter or other animal grease, and the skins are softened or leathered by tramping them in tubs, with a quantity of fine or veneer hard-wood sawdust, or in a tramping machine built on the principle of a fulling mill (see p. 292). This leathering is continued until the grease is driven thoroughly into the pelt, requiring from two to four hours in either the tramping tub or the fulling machine. The skins are then cleaned free of grease by revolving them with a quantity of fine sawdust, and this is in turn removed in the beating drum, thus terminating the operation of dressing.

Next comes the dyeing process. All holes and defective spots are first mended. If the pelts have been already partly shaved, a sheet of

paper is pasted on the flesh side; but if the pelt has been left thick, as is commonly the case, the paper pasting is omitted. The fur is treated with an alkali solution, followed by an acid mordant, for the purpose of "killing" the surface. Each establishment has its own formula for making the dye, the secret of which is usually carefully guarded. Formerly the fur was frequently bleached to a golden hue by means of chloride of calcium or peroxide of hydrogen, or, as was the usual practice in the United States, by a brushing of aqua fortis, over which hot irons were immediately passed; but this color is no longer fashionable. In most establishments the dye for the ends of the fur consist of various combinations of copperas, alum, salt, litharge, antimony, copper dust, verdigris, red tartar or argol, and salmiae. The ground color is formed of combinations of logwood, hippuric, fustic, nutgall, and iron liquor, in varying proportions, according to the experience and fancies of the dyer.

The fur is prepared for coloring by the application of a lime solution. Then the surface coloring is applied with a large brush, the points of the fur being carefully covered to the required depth. After lying folded, with the points touching each other for 6 to 12 hours, the skins are hung up and dried. When dry this dye forms a thin layer or crust, which is broken and beaten out with rattan sticks. Other coats of dye are then successively applied, dried, and the crust removed until the desired effect is secured. For the light brown shade formerly popular, 18 or 20 coats of the dye were necessary; but for the very dark shade popular at present fewer coats of a much stronger dye are used, the usual number applied being 8 or 10. Some years ago a process of dyeing was introduced by which the fur was dipped into the dye, which in this case must be hot. Fewer coats were necessary and a more brilliant color was imparted, but the texture of the fur was injured to some extent by the hot liquid.

When the desired shade is reached for the top of the fur, four or five coats of the more delicate dye are successively brushed on heavily and tramped in, forming a base or ground color. In tramping this ground color in, two pelts are placed together on the floor with the fur sides against each other, and the dyer lightly treads on them for two or three minutes. The skins are thoroughly cleaned with sawdust and all superfluous dye removed. The pelt side is then moistened with water and shaved down to the required thinness, removing all superfluous flesh and leather and leaving the pelt clean and free from dye. The skins are revolved in a cleaning drum, with maple or other lightcolored veneer sawdust for several hours, and on removal, and after beating free of sawdust, are ready for manufacture into garments.

While the foregoing is the general process, it is necessary to vary it for different skins, and successful dressing and dyeing require long experience and much judgment. Owing to the necessity for drying the skin a number of times in the dressing, and also after the applica-

tion of each coat of dye, the length of time required for both operations is six to eight weeks. The expense of this work in London is about 14 shillings, while in New York, owing to the higher price for labor and materials, it is about \$5 for each skin.

No matter how carefully the unhairing process is performed, a number of hairs are broken off near the surface of the fur, and there remain many of young growth and not yet above the surface, detracting from the beauty and softness of the fur, but adding thickness and durability, owing to the protection afforded. In the early history of fur-dressing in England and America these few hairs were left in, but when furseal increased in fashion it became important to have the fur as free from coarse hairs as possible. From 1870 to about 1882 the few hairs remaining after the process of depilation were removed commonly by hand labor, a slow and expensive process. Most fur-manufacturers employed girls to "pick" the skins. Blowing open the soft fur with her breath, the operator cut off the stiff, extended hairs with small shears, requiring one to five days for one person to complete a single skin.

Since 1883 most of this work has been done by complicated mechanism which accomplishes the work as effectually and far more expeditiously. In this process the skin is bent across the upper edge of a vertical board and the soft fur blown aside and divided by a thin, wide current of air from a bellows, when a pair of small knives descend and cut off the stiff, upright hairs. The knives are raised, the skin advanced the fraction of an inch, and the operation repeated until the entire surface is gone over, requiring about one hour to complete an average skin. This removal of the short hairs is invariably postponed until after the dressing and dyeing are completed.

On the adoption of fur-seal as a fashionable material, about 1870, and the great increase in price which quickly ensued, many substitutes were introduced, and since then few furs have been so frequently imitated. These were prepared from numerous cheaper furs, as otter, beaver, nutria, muskrat, conv. and even sheep. The otter, beaver, and muskrat imitations were fairly successful, especially for the manufacture of caps, gloves, and trimmings. They were not satisfactory for cloaks, the membrane being too thick and too weak to trim down sufficiently thin. The garments looked well at first, but soon showed wear, especially at the seams, and the dye faded. A large market was developed on the continent of Europe, especially in Germany and Russia, for fur-seal imitation prepared from muskrat pelts, this cheap substitute greatly injuring the market for the genuine material. Owing to the general dissatisfaction resulting from their use, these imitations were gradually abandoned by reliable furriers, and with the exception of that made from the French cony or rabbit, and known as "electric seal," "coast seal," "China seal," "Canadian seal," etc., fur-seal is not frequently imitated at the present time, except, as before stated, for trimmings and small articles.

FUR-SEAL SKIN, DRESSED, NATURAL.

FUR-SEAL SKIN, PLUCKED, NATURAL.

BEAVER FURS.

DESCRIPTION OF BEAVER SKINS.

During the seventeenth and eighteenth centuries the beaver furnished the principal item in the fur trade of the world, but at present it is of somewhat minor commercial importance among the aquatic furbearing animals. The skins received by the wholesale dealers from various localities shows different characteristics of pelage. In winter, the color on the back and sides is generally dark bay or brownish black, tipped with chestnut or russet, and seal-brown on the under parts, legs, and feet. The prevailing color ranges toward the south to a yellowish tinge upon brown, and in the north approaching a glossy blackish brown. In general, the beavers obtained in cold lati-tudes are darker than those secured in warmer climates, but those from the northwestern part of the United States are very light in color. A few black beavers and still fewer spotted ones are obtained; also, at very rare intervals, a vellowish white or pure white one is taken. The Labrador beaver, now somewhat scarce, is superior to those caught farther west, while those of Canada in general, as well as of the northern parts of the United States, are superior to those taken in the Southern States.

The overhair of the beaver is from $1\frac{3}{4}$ to $2\frac{1}{2}$ inches in length, rather stiff, and of a dull color for two-thirds of its length from the base, and is terminated by shining points ranging in color from the most delicate brown to rich, glossy blackish-brown, giving the general color to the pelage. The underhair or fur is very thick, fine, and soft, from onehalf to three-fourths of an inch long, and of a uniform bluish or brownish gray color from the roots to the tips. It is denser and shorter on the underparts than on the back. The fur becomes prime in October in the latitude of the northern boundary of the United States, and continues in good condition until May, when it begins to deteriorate. The pelts are marketable, however, till about June 15, although they are somewhat thin, light in weight, and of less value.

THE MARKETS FOR BEAVER SKINS.

The economic use of beaver pelts antedates the discovery of America. As far back as the Middle Ages, at least, beaver skins were used as clothing by primitive people in Europe. Their principal use, however, was as furnishing material for fashionable hats for men. Beaver hats were worn as early as the twelfth century, but their popularity was not permanently established until the sixteenth century, and then for more than two hundred years the beaver supplied the fashionable world with hat material. As the business increased, it resulted in the slaughter of hundreds of thousands of the animals, the market consumption in certain years approximating 400,000 skins, practically all of which were obtained from Canada and the United States. So extensive and regular was the beaver trade that in the

eighteenth and the early part of the nineteenth century the skins were accepted as currency throughout the western part of Canada and the United States and were the standard for bartering with Indians.

It was not long before the market demands outran the resources of nature and the beaver was in danger of extermination. The price of the skins increased correspondingly, selling at times for \$8 or \$10 per pound, and the finished hat for \$20 or more. At length the supply of the fur became so inadequate that other materials were necessarily substituted, resulting about 1839 in the general adoption of the silk hat by the fashionable world.

The demand from manufacturers of hats diminishing, the price of beaver pelts fell so low that the hunt proved unprofitable. Later a demand developed for the skins in the dressed-fur trade, and the price became steady at about \$2 or \$3 each. This fur became fashionable about twenty years ago, and the indications are that it will be in favor for many years. Small quantities, partly damaged in the curing, are yet used by the hatters, but its employment is mainly as dressed fur for caps, mufflers, gloves, trimmings, etc. Sometimes entire garments are made of it, but its weight makes it objectionable for that purpose. The darker pelts are usually purchased for the European and Canadian markets, while the medium and paler shades are worked up for consumption in this country.

The greater portion of the beaver skins taken on the American continent during the last 200 years have been handled at the London auction sales. The first sale occurred on January 24, 1672, and was an event of much importance. From that time to the present the total number of skins handled in London approximates 30,000,000 with a total valuation of \$100,000,000. The average annual sales at present approximate 50,000 in number.

In addition to those handled in London, about 20,000 beaver skins are now marketed each year, being sold at Leipsic and at private sale in the United States and Canada. This makes a total of about 70,000 skins marketed annually in recent years, of which about 10,000 are obtained in the United States and 60,000 in the Dominion of Canada.

In the markets, beaver skins are classed not only according to the general localities whence they are obtained, but also according to their size and the quality of the fur. In assorting them four grades are recognized. Those of the first grade have a flesh-colored pelt, which appears fresh and sound, and with long heavy fur, which separates down to the membrane when blown into and appears uniformly even, fine, and silky. The seconds are almost clear in the pelt and the fur only slightly scant or poor. In the thirds the fur is thin, scant and poor, and the pelt dark. Fourths are of the poorest quality, with pelt almost black or bluish-green color, and the fur short and thin. Each of these grades is divided according to size, the large, medium, small, and kitts. The prices range from \$1.25 for the poorest to \$10, \$12, and even 16 for those of choicest grade, averaging somewhat less than 6 per skin.

Fifteen years ago large quantities of beaver fur were used in this country, and as much as 65 per cent of that sold in London was purchased for the United States trade. At that time long garments were fashionable, and plucked and dyed beaver was much in demand for trimmings. During recent years, however, beaver fur has been largely out of fashion in the United States and Canada, and consequently the consumption in these countries has not been extensive.

DRESSING AND FINISHING BEAVER SKINS.

On arrival in the markets beaver skins are rough and greasy, with the fine rich fur almost concealed by the coarse brownish hair. In the process of dressing, the skins are first soaked in water over night. The following day each one is placed, flesh side up, on a flat, hard-wood beam, and with a breaking knife a workman breaks up the grain of the pelt, thus softening it. The pelts are washed with warm water and soap, and then prepared for plucking. The water is removed by passing them through either an ordinary roller wringer or a centrifugal wringer, or, in some houses, by pressing them with the breaking knife. The hair side is dried and warmed by artificial heat, care being taken to keep the pelt side damp; chalk is sprinkled over the surface, and the hair is removed in the general manner described on page 291. A very small percentage of beaver skins, probably not more than 1 per cent, are left "in the hair"-that is, the overhair is not removed. Only a small demand exists for natural beaver, however, owing to its rough and coarse appearance.

Formerly it was customary to shear beaver skins, instead of plucking them, and many are yet prepared in that manner on the continent of Europe. In this case it is unnecessary to moisten the pelt preparatory to plucking; but, placing the skin, flesh side down, on a beam and using a comb and shears, a workman clips off the greater part of the long hairs in much the same way as a barber operates. Beaver thus prepared bears some resemblance to sea-otter fur, especially when very dark pelts are used, and sheared beaver is often used in imitation of that costly fur. The imitation is greatly enhanced when the overhairs are whitened by means of an acid.

After plucking, the pelt is shaved with a skiving knife, as described on page 291, for the purpose of reducing its bulk preparatory to leathering. The pelt side is then dampened with cold salt water and allowed to so remain over night. The following morning it is stretched lengthways and crossways and partly dried. Butter or other animal grease is rubbed on the pelt side, and a number of skins placed in a fulling or tramping machine in which two hammers push or beat and turn them for eight or ten hours. The skins are then placed with a quantity of hard-wood veneer sawdust in a large drum, over either gentle charcoal fire or steam heat, and revolved for three or four hours. Next they are placed with sawdust in tubs, where they are tramped by barefooted workmen for about three hours, each tub containing about twenty skins.

On removal from the tramping tubs the pelts are thoroughly stretched by hand, and the leather side dampened over night preparatory to shaving on the following day. Shaving is the most difficult feature and is intrusted only to skilled workmen. Each skin is placed, fur down, on a perfectly smooth hard-wood beam, similar to that used in skiving, and by means of a skiving knife the operator shaves off the membrane of the pelt until the roots of the fur are almost visible.

The skins are again stretched lengthways and crossways by hand, dried, and for the second time placed in the tramping tubs with hardwood sawdust for further softening and leathering. After two or three hours' tramping they are removed, straightened or stretched out, and returned for two or three hours further tramping. They are next thoroughly beaten with bamboo sticks to remove the sawdust, and then combed with a fine steel comb to lighten up the fur. The skins are then placed on a beam and by means of a large flatbladed knife, sharp as a razor, a workman shaves over the top surface of the fur, removing all scattering hairs and impurities, thus completing the dressing process.

While it is not customary to dye beaver fur, many light skins are blended to a darker shade, and a few are dyed in nuch the same manner as fur-seal. Some few skins are bleached golden brown, and a smaller number to a creamy white. Some are silvered by passing lightly over them a solution of sulphuric acid, and some are made a golden yellow by means of peroxide of hydrogen.

About twenty years ago many beaver skins were "pointed," the plain solid color being ornamented by inserting white hairs at irregular intervals, in imitation of the pelage of the sea-otter or the silver fox. The hairs were generally sewed in the pelt by wig-makers, but in some cases they were firmly fastened with cement. Badger hairs were most frequently employed, but white hairs of the gray fox, cony, and skunk were also used. On account of its varied white tips, the hair of the Egyptian ichneumon was also in great demand, being superior to the hair of the fox, or even the badger. Some skins were likewise ornamented with the white tips of small feathers taken from the breast of the grebe and less frequently of the peacock. This ornamentation was quite fashionable from 1881 to 1884.

Beaver fur is especially serviceable for making hats because of its remarkable felting characteristics and its durability and glossiness. So strong are its felting properties that coats made from cloth of this material, manufactured solely by the felting process, have been known to wear for years, and it is claimed that in former times beaver fur was sometimes felted for hosiery purposes. While it is the most desirable of all furs for hat-making, its high cost prevents its general use for that purpose. Practically the only beaver fur now received by the hatters is the blown fur obtained from manufacturers' clippings and that cut from skins damaged in curing or otherwise, as has been already noted in the chapter on hatters' furs. But even in using fur from these sources, a light hat made from beaver can not be purchased for less than about \$10, and the price is likely to be \$15 or more.

MUSKRAT FURS.

DESCRIPTION AND CHARACTERISTICS OF FUR.

The fur of the muskrat is dense and soft, somewhat like that of the beaver, but is shorter and inferior in denseness, fineness, and durability. The color is generally drab blue, in some cases with a whitish appearance, and tipped with reddish brown. The fur of the small muskrat found in Alaska is of a light silvery color, almost white on the abdomen, and very fine, the pelts from that locality being highly prized when beaver hats were in fashion. The fur is concealed by long, stiff, brown overhairs on the upper surface and sides of the body. The general color of the animal is dark umber brown, almost blackish brown on the back and gray below, but specimens are found ranging through the various shades of brown, blue, and yellow to pure white.

In the Chesapeake and Delaware regions and, to a less extent, in other parts of America, in addition to those of the usual coloring, some individuals are very dark, so nearly black, in fact, that they are designated "black muskrats" in the trade. These are of superior quality and value. In some specimens, especially among those found in certain regions of Canada, the chest and abdomen is of a chestnut brown and in others almost white, but the latter are by no means common. Pure white muskrats are occasionally found, but they are of no more value in the trade than those of the ordinary coloring, although highly prized by collectors of natural-history specimens. As is the case with most aquatic mammals, the skins of those occurring in southern localities are thicker and more spongy than those in the colder latitudes. Muskrat fur is inexpensive, the skins selling usually for 10 to 20 cents each; however, under the skill of the fur-dresser and the dver, it assumes a high rôle in the form of imitations of more costly furs; in retail stores it is found prepared in so many different ways and with such a variety of finish as to be scarcely recognizable to the most expert trappers who are familiar with the raw skins only.

PRODUCT OF MUSKRATS AND THE MARKETS THEREFOR.

While the annual product of muskrats is at present very large, this extent is of comparatively recent development. During the eighteenth century the annual yield was relatively small and the fur was little prized. Many farmer boys found it convenient to set a few traps, using some of the skins for making caps, gloves, etc., and sending the rest to the market. The average quantity received on the market

throughout that century probably did not exceed 100,000 skins annually, although on three or four occasions the annual receipts at London exceeded 200,000, but in other years they amounted to only 25,000 or 30,000. During the second and third decades of the nineteenth century the output increased considerably, principally on account of the greatly increased market value and the opening up of new trapping territory. In 1829, for the first time, the London receipts exceeded 1,000,000 skins, the total being 1,165,663. The annual receipts thereafter fluctuated greatly, but on the whole continued to increase, exceeding 2,000,000 in 1862, 3,000,000 in 1867, and 4,000,000 in 1871. Since the year last named, the price of the skins has greatly decreased, but the receipts at London have been fairly constant, averaging about 3,500,000 annually.

In addition to those handled at the London sales, about 2,000,000 muskrat skins are placed on the markets each year. Of these, 1,500,000 pass through Leipsic, and 500,000 are sold to the furriers of the United States and Canada without passing through the two large market centers. This makes an aggregate of over 5,000,000 skins annually, of which nearly one-fourth are obtained from the Dominion of Canada and the remainder are caught in the United States. The total product of muskrat skins in the United States and Canada during the nineteenth century reaches the enormous amount of 250,000,000 in number, sufficient to make a blanket covering nearly 4,000 acres.

Formerly the fur of the muskrat was used largely as a substitute for that of beaver in hat-making, forming a cheap and fairly satisfactory imitation. Owing to its scarcity it was then of much greater value than at present, selling for 40 or 50 cents per skin, even equaling the value of the mink at times. The general adoption of the silk hat resulted in a great decrease in the demand, and the price fell as low as 6 or 7 cents per skin, and trapping then was of little profit. During the last sixty years muskrat has been used principally as dressed fur, prepared in imitation of the more highly prized beaver, otter, and fur-seal. It is about the best of all the cheap furs.

In the market muskrat skins are classed as "firsts," "seconds," "thirds," "fourths," and "kittens." The firsts are those caught during the spring or very late winter; seconds are caught in midwinter; thirds, those taken in very early winter or fall; fourths, in early winter or fall, and are poor and small; and kittens are those less than 3 or 4 months old. The value of the skins varies from 5 to 40 cents each, according to color and condition. Those from the Chesapeake average about 14 cents each for brown and 25 cents for black. The black pelts are marketed principally in Russia, where they are used for coat linings, but many are used in England, France, and America for cloaks, trimmings, and gloves. The price of the No. 1 black skins at the last London sales averaged 1s. 3d.; in 1891 it was about 1s. 7d., while in 1875 it was over 3s. The lighter skins fetch about 7d. each.

DRESSING MUSKRAT SKINS.

At the fur-dresser's, muskrat skins are first dampened on the pelt or flesh side with salt water and permitted to so remain over night, for the purpose of softening. The following morning the skins are placed in a tramping machine, where they are fulled or tramped for eight or ten hours. Formerly the tubbing process was used, but the tramping machine is much more economical and is now employed for these skins by nearly all dressers. In tubbing, a good operator can work 100 muskrat pelts in a day, whereas a tramping machine can work 2,000 in the same length of time.

The pelts are next covered with a mixture or paste of sawdust and salt water and so remain over night. The water is used to keep the pelt soft, the salt to prevent the hair from falling out in the heating. and the sawdust to hold the moisture. The following morning the skins are cut open down the front, provided they are cased, as is the general rule, and are then fleshed, in the manner described on page 292, one man being able to flesh 200 to 300 per day. They are now stretched lengthways and crossways and hung up to dry. When thoroughly dry, in the leather as well as in the hair, they are again moistened with salt water on the leather side, remaining thus over night. They are next brushed on the leather side with animal fat. such as butter or fish oil and tallow, most of the grease being placed in the center, and the skins laid in pairs with the hair side out. After remaining thus over night, they are placed in tramping machines and worked constantly for 6 or 8 hours or until thoroughly soft and pliable. On removal from the tramping machines the skins are stretched in every direction.

At this stage the fur has a dirty, greasy and uninviting appearance, the grease and sawdust having worked into it during the preceding operations. The skins are placed in quantities of 300 or 400 with sawdust in revolving cleaning drums; where, exposed to steam heat or charcoal fire, they are revolved for about three hours, the sawdust by that time having completely absorbed the grease, leaving the fur clean and soft. They are next inclosed in a beating drum, previously described (see pp. 293), where they are revolved for two or three hours. On removal they are beaten with rattans and the fur cleaned with a comb. The pelt of many muskrats is quite thick, and these are selected out at this stage of the process and fleshed down, thus completing the operation of dressing with the exception of plucking.

Plucking is performed the same as in case of beaver pelts, except that it is done after the pelt has been dressed rather than before; after plucking, the fur is again cleaned and the process is ended. Twenty years ago 85 per cent of the muskrats were plucked, but at present the conditions are reversed and only a very small percentage are so treated. Indeed, on one occasion the writer spent nearly two hours

among the furriers of New York in fruitless quest of a plucked muskrat skin, visiting eight or ten of the principal establishments, and finally was obliged to have one specially plucked for his use.

For the home dressing of a small quantity of muskrat skins the following has been recommended: After washing them in warm water, all fatty and fleshy matter is carefully removed. In a liquor composed of 10 callons of cold soft water, 8 quarts of wheat bran, 1 pint of old soft soap, 1 ounce of borax, and 1 pound of salt, the skins are soaked eight or ten hours if they are fresh, or until very soft in case they have been previously dried. The salt should be omitted from the solution if the skins have already been salted, and the addition of 2 ounces of sulphuric acid to the solution will prepare them in about one-half the time. The skins should then be soaked in a liquor made of 10 gallons of warm soft water, ½ bushel bran, and 2½ pounds sulphuric acid. The bran should be stirred in the water until thoroughly mixed, and then left to stand in a warm room until it ferments, when the sulphuric acid is added by degrees and with constant stirring. After soaking in this liquor for about four hours, the skins are removed and rubbed with a fleshing knife and then over a smooth beam until dry.

Muskrat fur is used more extensively in Europe than in America, the Russians and Germans being especially large consumers. It is employed in making gloves, collars, capes, muffs, trimmings, linings, etc., and is made up either natural, plucked, plucked and pointed, or plucked and dyed black or various shades of brown. Large quantities are used as linings for overcoats and long wraps, from forty to sixty being necessary for each garment. Sometimes the under parts are used separately for this purpose, the natural bluish-white color being quite effective. The skins of young animals are especially suited for linings. The unplucked skins are frequently dyed to imitate mink, and sold as Alaska mink, water mink, or black mink.

Two or three decades ago quantities of muskrat skins were plucked and dyed to imitate fur-seal, the resulting article readily deceiving the uninitiated. While the fur is soft and short, it is not as thick as that of the fur-seal, and the leather is much heavier and not sufficiently strong to permit its being scraped to a suitable thinness. After a few weeks' wear the fur becomes matted down, being less elastic than seal fur. During the eighties the use of muskrat for this purpose was extensive, especially in Europe, thus providing a large market for this abundant and easily procured fur. It injured the popularity of fur-seal, persons hesitating about paying \$200 for a garment when a fairly good imitation was obtainable for one-fifth of that amount. The imitation, however, was generally unsatisfactory to the trade, and on the introduction of "electric seal," made from the cony, the use of muskrat pelts for this purpose was generally abandoned, except for small articles, as gloves, caps, etc.

FUR OF THE COYPU OR NUTRIA.

Somewhat similar to the beaver and the muskrat is the coypu, sometimes called the South American beaver. In the fur trade it is known exclusively as nutria, from the Spanish *nutra*, the otter, owing to the similitude of its fur to that of the otter. It inhabits the river banks and low lands of South America, and is most numerous in the vicinity of Rio de la Plata. The hunting season is from May to October, and after the pelts have been cured by drying they are sold to traders, who bale and ship them to Hamburg, London, and New York.

Nutria fur is short and silky, and except on the back is quite thick, being choicest underneath the body. Its similarity to beaver fur is noticeable, differing principally in being much shorter and less brilliant. The overhairs are bristly, from 1 to 3 inches in length, and of a brownishyellow color. This fur was introduced in commerce about 1810, as a substitute for that of beaver in hat-making. After the silk hat came into fashion, nutria was gradually adopted as a dressed fur and, as in case of muskrat, largely in imitation of beaver, otter, and fur-seal. Probably one-third of the output is yet consumed in hat-making, being used for choice grades of soft hats.

The product fluctuates considerably, but is always large. Two or three generations ago five or six million skins were sometimes shipped from South America in a single season, and over 5,000,000 have been received at New York in one year. Owing to imperfect curing, or improper storage afterwards, many of the pelts arrived in faulty condition and were suitable for little other than glue manufacture. The abundance of the animals was greatly reduced, and at the same time. owing to conditions in the hat trade, the value of the fur decreased, so that the output shrank from 6,000,000 pelts annually to about onetenth of that number. But during the last two or three years the output has been much greater, amounting in 1900 to somewhat less than 2,000,000 skins, obtained principally from the valley of Rio de la Plata. It is estimated that about 75 per cent of the product is used in the United States. Owing to the varying supply, the price has fluctuated considerably, ranging from \$4 to 30 cents per pound. The skins are usually sold by weight, one of fair size weighing 6 or 8 ounces.

The dressing is quite similar to that of beaver skins, the principal difference being that the pelt of the nutria is not "broken" (see p. 291), the overhairs are pulled out by the picking knife instead of with the beaming knife, the pelt is fleshed instead of being shaved, and it is oiled after fleshing instead of before. These differences in treatment are due principally to the greater thinness and weakness of the pelt. In dressing, the nutria skins are soaked in water overnight and washed thoroughly in warm soap water until the membrane is perfectly clean. The water is then removed and the skins prepared for plucking by drying the fur and overhair, at the same time keep-

ing the pelt moist. The overhairs are removed principally by hand, the workman pulling them out by grasping them between a dull knife of soft metal and his thumb, protected by a rubber cot. Practically all nutria skins are plucked, it being difficult to find a single dressed unplucked skin in New York.

If convenient, the pelts are soaked again overnight in cold water, and then fleshed by drawing each one successively across the edge of a large vertical knife (see p. 292). After fleshing, the skin is brushed on the pelt side with strong salt water, and after remaining in that condition over night, it is treated in much the same manner as a beaver skin. It is moistened on the flesh side with some animal grease, preferably butter, worked in the tramping machine or the tramping tub, the grease removed by revolving in a drum with sawdust, and the skin freed from sawdust in a cleaning drum. It then goes to the picker, who places it upon a beam and skims over the surface of the fur with a large flat-bladed knife having a razor-like edge, removing the remaining hairs, thus completing the process.

Nutria fur, natural, plucked, or plucked and dyed, is used for all the purposes of beaver fur, and the choicest can be distinguished from the latter only by experts, being nearly as fine and durable. It is used principally as a dressed fur, the overhairs being removed and the fur dyed dark brown, affording one of the best imitations of fur-seal for small articles. It is also dyed various other shades of brown, and occasionally is silvered with acid as in case of beaver furs.

OTTER FURS.

CHARACTERISTICS OF PELAGE.

The fur of the otter is short, abundant, and of fine quality. It is slightly waved and silky and is similar in appearance to that of the beaver, but is somewhat shorter and more delicate and glossy. The fur on the stout tail is of the same character as that on the body, but not so long. That on the body is of a whitish-gray color for two-thirds of its length from the base, rich brown at the tips, and is interspersed with stiff, thick overhairs similarly colored. The general color of the overhairs is brown above and a little whiter beneath, with chin and throat whitish. The shade of brown varies according to the locality in which the animal lives; in eastern Maine this is almost black; in Canada, Nova Scotia, and Labrador it is dark brown; in Alaska and British Columbia the animal is light brown. The fur on the throat, under parts, and inner surface of the legs is usually of various shades of brown. White or albino skins are occasionally secured, and silvery, grizzly, mottled, and slate-colored are met with at times.

TRADE IN OTTER SKINS.

The early trade in otter skins in America, although never so extensive, was almost contemporaneous in its development with the trade in beaver furs. In the operations of the early fur-traders in the present limits of the United States many otters were obtained. It appears, however, that the capture of these was merely incidental to the taking of beaver. Indeed, during the first hundred years of the exploitation of America the beaver was almost the only fur-bearing animal whose capture was a special object of industry. Later, however, with the increase in value of the pelts, the otter became an object of special pursuit, and by 1777 the industry reached an extent from which it has varied little up to the present time.

It is quite remarkable that the number of otter skins which are handled annually at the London sales should have fluctuated so little during the last 140 years. From 1763 to 1900 the annual quantity exceeded 30,000 only twice, and it fell short of 8,000 the same number of times, and the average by decades is nearly the same throughout the last 120 years.

With the exception of the nutria, a smaller proportion of the total product of otter skins are now handled at the London sales than in case of any other aquatic fur, only about one-third of the American product being sold there. The others are sold at Leipsic or directly to the furriers of the United States and Canada. The best local markets for otters are in Russia and Greece, where the fur is much used for caps, collars, and trimmings.

Out of a total of 7,865 otter skins sold in London in March, 1901, 3,293 were No. 1; 2,498 were No. 2; 1,318 were No. 3, and 756 were cubs. The No. 1 averaged in value 28s. 6d.; the No. 2, 20s. 6d.; the No. 3, 12s. 1d., and the cubs 5s. 6d. per skin. These prices were somewhat less than the average in 1900. The highest price secured at the 1901 sale was 115s. each for a lot of 42 skins, while the lowest price was 3s. each for a lot of cubs, and also for a number of part pale No. 3. Exclusive of the cubs, those of a brown color numbered 269, while 301 were partly brown, 693 pale, 1,691 partly pale, and the remaining 4,155 of the distinctive dark otter color.

DRESSING OTTER SKINS.

When received at the fur-dresser's, otter skins are almost invariably cased, and are first cut open longitudinally down the chest and abdomen. The pelt is soaked in salt water over night for the purpose of softening it and preparing it for "breaking." The following morning each skin is placed on a beam, and a workman proceeds to break up the grain of the membrane by the process described on page 291. The pelt is now washed in warm soap water and the water removed, as in case of beaver skins. (See p. 311.) If the overhairs are to be plucked, that is done next. The choicest skins are left "in the hair," the number amounting to about a third of the total quantity dressed. The plucking is done in the manner described on page 291.

The pelt, which has become less bulky and quite soft from frequent handling, is now placed on a beam and skived in the general manner

further described on page 291. It is next dampened with cold salt water and allowed to thus remain over night. The next morning it is stretched lengthways and crossways and partly dried, when it is ready for the leathering process. It is well rubbed with butter, or some other animal grease, and placed with others in a tramping machine. where it is worked for hours. On removal the skins are revolved for three or four hours with a quantity of hard-wood sawdust in a cleaning drum, under which there is steam heat or a charcoal fire. Next they are placed in tubs with a quantity of sawdust, where they are tramped for about three hours by barefooted workmen and on removal are thoroughly stretched. The leather side of the pelts is dampened over night and then shaved down to a uniform thickness as in case of beaver skins. (See p. 311.) A skillful workman can shave 30 or 40 otter pelts in a day. The skins are then stretched, dried, and placed for a second time in tubs with hard-wood sawdust and tramped for two or three hours, then removed, stretched again, and returned for two or three hours' further tramping, and then the fur is straightened out with a fine steel comb. The skins now receive a thorough beating with rattans to remove every vestige of sawdust and to lighten up the fur. If they have been unhaired, they go to the workman who removes all scattering hairs by means of a broad-bladed knife.

The methods of dressing otter furs have been greatly improved in this country in recent years, and the reputation of American workmen in this particular is preeminent. Otter skins having coarse overhairs are greatly improved in appearance by plucking, as the fur is extremely soft and dense. When plucked, the fur is used either natural or dyed various shades of brown. A few skins are clipped. This fur is very durable, the leather being strong and fine-grained. In the natural state choice otter makes rich trimmings for seal sacques; and the plucked fur, both plain and dyed, is used for caps, gloves, capes, and garments. The skins are also used for coat collars and storm coats, more especially in Europe. In Scotland many are used in making the characteristic sporrans.

During recent years otter has been extensively dyed in imitation of the fashionable fur-seal, being cheaper than the latter, and when carefully and newly prepared can be distinguished only by experts. The price of good otter skins and the cost of dyeing the same is so great that these dyed skins have cost nearly as much as fur-seal. This has retarded their popularity, but with the advancing price of fur-seal dyed otter will doubtless find a larger market. In appearance it is the equal of seal skin and its wearing qualities are excellent. It is desirable to dye otter skins while in the raw state, as the grease prevents the dye from penetrating and injuring the leather, which would be weakened if the dye were applied after the skin had been dressed. Only the heavy-furred skins are selected for this purpose.

NUTRIA SKIN, DRESSED, NATURAL.

MUFF OF MINK SKIN, SHOWING METHOD OF SEWING AND PIECING.

SEA-OTTER FURS.

The sea-otter yields the most valuable of all aquatic furs. The skins are of the greatest value in the third or fourth year of age, when the overhairs are scanty, exceedingly fine, and extend but little beyond the fur, which is unusually dense, fine, and silky. There appears to be little difference in the quality of the pelage at different seasons of the year. The glossy, durable fur is about three-fourths of an inch in length all over the body, except that on the feet, head, and tail it is rather shorter, finer, and with fewer overhairs. The under portion of the back, the nose, and the upper lip are the only naked parts.

The color of the pelt varies considerably, the predominant shade being lustrous brown brightened with silvery overhairs. Some pelts are a deep brown or a brownish black, and are known in the trade as "black." Others are brown, with a tendency toward bluish green or dark-plum color, and are known as "dark." The fur is in all cases lighter on the abdomen than on the back. The hair on the head is lighter in color, and is light brown in the brown variety, but in the black animals it is almost completely white, the effect of the large number of white overhairs. The skins from British Columbia, Washington, and Oregon are frequently of a yellowish-brown hue, and albino skins have been taken rarely.

The choicest sea-otters have dense, brownish-black fur of silky, shimmering gloss and extreme fineness, exhibiting a silver color when blown open and with a reasonable number of white hairs regularly distributed, too many white hairs depreciating the value of the pelt. The skin of the male is usually more valuable than that of the female, being more brilliant and velvety in appearance. After they pass the age of perfection the fur becomes a dingy brown.

The skin is remarkably loose, like that on the neck of a young dog, and 12 inches or more of slack may be gathered in the hands from most parts of the body, the pelt of an individual 3 feet long readily stretching to 5 feet. A full-grown prime skin, which has been stretched before curing, is about 6 feet long and 24 to 30 inches wide.

The sea-otter belongs exclusively to the shores of the North Pacific Ocean and the adjacent seas, its range extending from Bering Sea southward to Japan on the Asiatic coast and possibly to Mexico on the American coast. It was formerly quite abundant throughout that region, but its numbers have been so reduced by excessive hunting that it is now very rare and in great danger of extermination.

The territory within which sea-otters are at present taken extends along the American coast from the Aleutian Islands southward to Washington, and on the Asiatic coast from Kamchatka to Japan. In most of that region, however, the catch is exceedingly limited, the annual product on the entire coast of the United States, exclusive of Alaska, for instance, not exceeding one dozen. The bulk of the catch is obtained now, as 100 years ago, among the islands of southeast Alaska.

F. C. 1902-----21

The total product of sea-otter skins, obtained from the North Pacific since the development of the hunt, about two hundred years ago, approximates 700,000, made up as follows:

| By whom obtained. | | | | |
|---|---|--|--|--|
| Russian traders, previous to 1707 Russian American Co., 1798–1867 Miscellaneous traders, 1785–1822 Miscellaneous traders, 1829–1967 Miscellaneous traders, 1868–1960. | $130,000 \\ 160,000 \\ 250,000 \\ 15,000$ | | | |

Assuming that these skins cost the consumers an average of \$150 each, we have a total of \$105,000,000 expended for sea-otter furs, of which doubtless over 95 per cent came from residents of China and of Russia, and probably more than 80 per cent from the Chinese alone. A single skin has sold for \$1,400, and though that is a fancy price, \$700 or \$800 is not unusual. The value is determined by the size, richness of color and texture, and the depth of the blackish hue studded with a suitable number of silvery hairs. The market value has varied somewhat from year to year, but has been high ever since the origin of the traffic in these furs. At the time of Cook's celebrated voyage to the North Pacific in 1778, the price of a prime skin was about \$120 in China. In 1802, when the largest collection was made-25,000 skins-the average price of large and small at Canton was about \$50 each. In 1840 prime skins sold readily for \$150 each out of the vessel. The average price of all skins at the London sales in 1888 was £21 10s.; in 1889, £33; and in 1891, £57; but the first-quality skins fetched much higher prices. At present, pelts average in value £65 each, including cubs as well as prime skins, while choice specimens readily fetch £200 each.

Seldom do the choicest sea-otter skins enter into the retail trade in America or England; and although the greater part of them are caught within the limits of the United States, it might be difficult at times to find a dozen skins in all the fur stores of the country. This fur has ever been held in high estimation by the Russians and Chinese, but the great cost limits its use to the wealthy classes exclusively. It is the royal fur of China, being worn by officers of State, mandarins, and other persons of importance in the Celestial Kingdom. In Russia it is used principally for the collars of overcoats. Sea-otter fur is also used for making muffs and for bordering fine garments made of textile fabrics or of other costly furs. Owing to its great weight as well as cost, entire wraps are rarely made of it.

While many sea-otter skins are marketed in Asia and Russia, probably 80 per cent of them pass through the London auction sales held in March of each year. The large decrease in the abundance of these animals is well illustrated by the decreasing numbers offered at those sales, the quantity sold at present being little more than 10 per cent of what it was twenty years ago.

UTILIZATION OF THE SKINS OF AQUATIC ANIMALS. 323

The following shows the quantity offered at those sales during each of the last thirty years:

| Year. | No. of skins, | Year. | No, of skins, | Year. | No. of skins. |
|--|--|-------|--|-------|---|
| 1871 1872 1873 1873 1875 1875 1875 1877 1877 1878 1879 1880 | $\begin{array}{cccccccccccccccccccccccccccccccccccc$ | 1881 | 5, 647 5, 657 5, 680 5, 038 4, 908 4, 804 4, 413 4, 352 3, 511 2, 713 | 1891 | $\begin{array}{c} 2,329\\ 1,368\\ 1,788\\ 1,583\\ 1,521\\ 1,550\\ 1,201\\ 955\\ 760\\ 584\end{array}$ |

The sales of Messrs. C. M. Lampson & Co., London, for March, 1901, included 409 sea-otter skins," of which 145 were large black skins, which sold at prices ranging from £52 to £280 each, or a total of £12,585 for the 145. The next largest class was a total of 118 large dark skins, varying in price from £48 to £125 each, or a total of £7.640. Only 14 brown skins were offered at that sale, of which 13 were large and 1 was of medium size. Out of the total of 409 skins, there were 276 large ones, the others consisting of 96 medium, 25 small, 1 extra small, and 11 cubs. The average value of the large skins of all classes was £75 6s, 7d.; of the medium size, £50 8s, 10d.; of the small size, £35 6s. 5d.; of the extra small, £12; and of the cubs, £2 1s. 10d. Four very small cubs sold for 10 shillings each. While it is extremely gratifying that the large skins formed so high a percentage of the total number, yet it is to be regretted that there were any small skins whatever, and the taking of cubs was wanton destruction of valuable resources. The prices realized in 1901 were practically the same as in 1900, when 584 sea-otter skins were offered.

The following summary shows for each grade of skins at Messrs. C. M. Lampson & Co. March, 1901, sale, the number sold, minimum and maximum prices, total selling value, and average selling value:

| Designation. | No. of skins. | Minimum price. | Maximum price. | Total value. | Average value. |
|-------------------|------------------|-------------------|-------------------|-----------------|-------------------|
| Large, black | 145 | £52 | £280 | £12,585 | £86.79 |
| dark | 118 | 48 | 125 | 7,640 | 64.75 |
| brown | 13 | 38 | 68 | 570 | 43.85 |
| Medium, black | 43 | 40 | 75 | 2,258 | 52.51 |
| dark | 52 | 32 | 70 | 2,549 | 49.02 |
| brown | 1 | 36 | 36 | 36 | 36.00 |
| Small, black | 11 | 32 | 42 | 393 | 35.73 |
| dark | 14 | 30 | -40 | 490 | 35.00 |
| Extra small, dark | 1 | 12 | 12 | 12 | 12.00 |
| Cubs | 11 | 1/2 | 3 | 23 | 2,09 |
| Total | 409 | | | 26,556 | 64.93 |

DRESSING SEA-OTTER SKINS.

The sea-otter should be skinned as soon as practicable after killing, and if caught far from the shore or from the vessel it should be laid out smoothly in the bottom of the boat and covered over with seaweed

aA total of 422 were offered, but only 409 were sold. This comprises the bulk of the sales of seaotters throughout the world for that year.

or otherwise protected. In skinning, a cross slit is made down the hind legs and a longitudinal cut made along the under side of the tail throughout its length, and the pelt drawn flesh side out over the body and head without cutting along the abdomen. No fur whatever is left on the carcass—tail, legs, and head being carefully stripped of their covering, though the fur on the legs and head is of relatively little value. The pelt, with the fur inside, is then tightly stretched on a stretching board. The fat adhering to the flesh side is carefully removed, the holes made by spears, or otherwise, carefully sewed up, and the pelt placed in the open air, protected from the sun, to dry. When quite dry, the fur is combed and the pelt rolled up and stored in a safe place, whence it is occasionally removed and examined for moths, etc.

The present method of dressing sea-otter pelts is much less complicated than the treatment of beaver or mink, but, owing to the great value of the fur, extreme care is taken at all stages. The flesh side is first dampened over night with salt water, and then greased with choice butter, and several skins at a time tramped in a foot tub for four or five hours. Fine hard-wood sawdust is then added, and the tramping continued for two or three hours longer. On removal they are moistened with soap water over night and then shaved to thin the pelt, the same as in dressing beavers. Next they are worked in a tramping tub with fresh sawdust for two or three hours, and on removal are cleaned of sawdust, either in a beating drum or by striking with rattan sticks. After combing with a fine steel comb, the skins are ready for delivery. Owing to the care necessary in the process, the cost of dressing seaotter skins is about \$2 each, compared with 50 cents each for those of beaver and otter. Unlike other cased pelts, sea-otters are rarely ever cut open at the fur-dresser's.

MINK FURS.

The pelage of the mink consists of dense soft fur, of excellent quality and nearly uniform on all parts of the body, overtopped by stiff, lustrous hairs about three-fourths inch long. The color shows marked variations, ranging from a light dull-yellowish brown to a dark brownish black, but is ordinarily of a rich dark brown or chestnut brown glossed with black. It is usually slightly darker on the upper parts than below, the back and tail being the darkest, and the gloss is also most marked in the fur of the upper parts. The choicest are nearly black, approximating the desirable hues of sable, these being generally from New England, the wooded districts of Nova Scotia, and the Province of Ontario. The lighter colored are of less value, and are usually dyed or blended to the desired dark shade. Albinos, as well as mottled and drab-colored pelts, are occasionally secured. Sometimes skins with white hairs sprinkled in the brown fur are obtained. Often there is a white spot on the throat similar to that of the marten, and a white spot or line of varying length sometimes occurs under-

MINK SKINS CASED AND DRESSED.

neath. At times the long, bushy, and somewhat tapering tail is tipped with white. Minks from southern localities generally have fuller and thicker tails than those from farther north.

The fur is generally dark bluish-brown and sometimes dark blue in case of very dark pelts. It is dense, glossy, short, and exceedingly durable, making it one of the most economical furs in use. The skin is very thin, the thinnest of all the aquatic fur-bearers, yet it is very tough. The mink pelts from cold localities are the choicest and most brilliant; those from southern regions are coarser, harsher and with less difference between the fur and the overhair. They are marketable only when taken late in autumn, in winter, or early in spring.

When the fur of the mink was very fashionable and correspondingly high in price thirty years ago, several attempts were made to raise these animals in confinement. But it was found difficult to rear them when large numbers were kept together, the breeding being reduced and the females quarreling and fighting and frequently killing the young. Practically all these experiments ended in failure.

MARKETS FOR MINK SKINS.

Few furs surpass that of the mink in richness of coloring, quality, and durability; yet, owing to the capriciousness of fashion, it has frequently sold at a comparatively low price. It furnishes a striking example of the vagaries of fashion in the fur trade. Formerly it was used almost solely for imitating marten. About 1860 the fashionable world took a fancy to it for cuffs, collars, trimmings, and even for garments of various sorts, resulting in increasing the market price of the pelts from about 50 cents each to \$8, \$10, or even \$20 for very choice skins. A mink muff of good quality sold for \$75 or \$100, and a full-depth mink wrap sold at times as high as \$1,500. Indeed, during the sixties, it was the leading fashionable fur of this country. Then its popularity gave way to fashion's demand for change of color and shorter pelage, and the price of prime skins decreased from \$15 each in 1864 to \$8.50 in 1866, to \$3 in 1878, and to \$1.25 in 1883. For many years the mink was out of favor and it almost disappeared from the market, But among those who could be independent of fashion, -this warm, durable fur maintained its former popularity. -It is now somewhat more in demand, but is moderately cheap compared with prices prevalent thirty-five years ago, rarely selling for more than \$3 each wholesale, except for very choice skins. In consequence of its many good qualities, it merits much greater popularity than it enjoys.

About 400,000 mink skins are sold in London each year. This represents about 55 per cent of the total product of mink, the other skins being disposed of at private sale to furriers in Europe and America. About 80 per cent of the total product is obtained from within the limits of the United States, the remainder coming principally from Canada.

DRESSING MINK SKINS.

Mink skins as received at the dresser's are usually cased, the fur being turned inside and only the greasy skin appearing, and they usually remain cased during the entire operation of dressing. As may be required, the fur and the leather sides are successively turned outward, and this tedious process forms one of the principal items in dressing this fur. The first operation is to place each pelt on a beam and scrape or beam off all the grease and surplus flesh adhering to the membrane. They are next moistened on that side with salt water. After remaining thus overnight they are placed in a tramping machine, 2,000 pelts at a time, and revolved for four to six hours. until they are thoroughly softened. In the best establishments, the same result is accomplished in the tramping tubs. They are next turned fur side out and cleaned in a revolving drum containing sawdust and a few handfuls of plaster of paris or fuller's earth. This is continued until the grease is entirely removed, when they are revolved in the beating drum and the sawdust, etc., removed.

On removal therefrom the skins are turned leather side out, moistened with salt water over night, then fleshed, as described on page 292. After fleshing, they are stretched as wide as possible with special iron stretchers, hung up and dried. The following day they are placed in the foot tubs—100 skins and 1 peck of sawdust to each tub—where they are treaded by barefooted workmen for about three hours. On removal they are stretched lengthways and beaten with rattans or in a beating drum. Then they are turned fur side out, placed in the cleaning drum with fine hardwood sawdust and revolved until thoroughly clean, which may require five or six hours. They are again placed in the beating drum to remove all the sawdust. On removal therefrom the fur is combed straight and they are turned leather side out and cleaned and polished with a fleshing knife, or, according to more recent practice, on an emery wheel.

Mink fur is manufactured into muffs, wraps, gloves, caps, and boas, either in natural state or dyed. Many skins are also used for coat linings. The tails are usually made into capes. Mink pelts are never plucked unless the overhair is exceptionally poor. This fur is very durable, lasting with moderate care a generation or more. The writer recently examined a mink muff "almost as good as new," which had been in use for more than fifty years. Mink fur is very frequently sold under the name "American sable." Report U. S. F. C. 1902.

AQUATIC LEATHERS.

GENERAL REVIEW.

The crude skins and hides of aquatic as well as of land animals are easily putrescible when left in a green state, and if dried they lack suppleness, and are hard, unpliable, and almost impermeable to air. Leather, on the contrary, is one of the most imperishable of animal products, and is supple and porous to a greater or less extent according to the process of manufacture. To transform the crude skins into leather is the business of the tanner and the currier; the former removes the tendency to putrefaction and incidentally increases its strength, durability, and imperviousness to water, and the currier renders it soft and pliable and at the same time imparts to it such finish and coloring as suit the special purposes for which it is intended.

Leather is made from the skins of practically all the aquatic mammals and of some species of fishes; but at the present time, except among primitive people whose stock of raw materials is limited, these products rank among novelty or fancy leathers. Ordinarily the supply of aquatic animals yielding skins suitable for tanning is so small or so difficult to obtain, compared with the enormous quantities of domestic animals available, that the leather made from the former can not compete in price with that from the latter. The nearest approach to competition is in the case of seal leather, of which large quantities are produced each year, the value of the annual product averaging \$1,500,000; but the durability and choice grain of this article secures for it a much higher price than is obtainable for a good quality of The hide of the beluga, or white whale, is one of the best calfskin. of all skins for leather purposes on account of its durability, strength, and pliability; it is sold as porpoise leather, and probably \$200,000 worth of tanned hides are marketed annually. Alligator skins are also obtained in large quantities, and, owing to the peculiarity of their markings, are used entirely as fancy leather; the total value of the output amounts to about \$500,000 annually. Tanned walrus hides, and especially the thick ones, are in great demand for polishing wheels and other mechanical purposes, and probably \$100,000 worth are sold annually. These are the only aquatic leathers which at present have an established position and a fairly constant price in the markets, but they are not the only aquatic leathers obtainable, the writer having collected 31 other varieties, although these are used in such small quantities that no constant market exists for them. Among those used to a less extent may be mentioned sea-lion, porpoise, sea-elephant, manatee or dugong, water moccasin, frog, otter, beaver, beaver tail, muskrat, and a variety of fish skins.

The art of the tanner has been so developed that the preparation of certain skins in imitation of others is by no means a difficult process.

The hides of walrus, sea-lion, sea-elephant, etc., are generally so damaged by the animals fighting among themselves, and from other causes, that, while the raw pelts may be abundant and cheap enough, it is difficult to secure them sufficiently free from defect to permit of their use as fancy leathers with economy. On this account, seal skins, which are comparatively free from the objection noted, are generally used to imitate those leathers, the tanning and currying process being so modified as to develop the peculiar grain desired; and while there is much genuine walrus leather, sea-lion leather, etc., the great bulk of that on the market sold under those names is made from seal skins.

The skins of fish are generally glutinous and soluble in water, but the texture of most of them is sufficiently firm and strong to permit of their use as leather, although their employment for practical purposes is rather limited. Skins of cusk, cod, eels, flat-fish, and the like, have been converted into leather suitable for gloves, purses, boot tops, etc. The tubercular skins of many sharks, rays, and allied fishes are largely employed under various names for polishing purposes and for covering boxes, sword grips, etc. All of these miscellaneous skins are valued principally because of their peculiar grain or markings, and are tanned so as to bring the grain into prominence. Their use is principally in small articles as belts, cardcases, pocketbooks, and the like. Recently they have been applied to the artistic binding of books, planned at the suggestion of Mr. George F. Kunz. Among these was the catalogue of the Izaak Walton exhibition at the Grolier Club, New York City, in 1894. Beautiful effects have been secured by the use of variously colored shark skins, polished to a smooth surface and frequently inlaid with some other material. The possibilities for the development of this use of fish skins are remarkable.

Fish skins are employed extensively in the preparation of glue and fertilizer stock. Especially notable in this connection is the waste from the New England factories engaged in preparing boneless codfish in the forms of bricks, and thousands of dollars' worth of skins of cod, hake, haddock, etc., are annually converted into fertilizer and glue.

GENERAL METHODS OF PREPARING AQUATIC LEATHERS.

Leather manufacture is of great antiquity. A process of tanning, differing principally in detail from that practiced at the present time, was doubtless followed long before the days of Simon the tanner. While its kindred industrial arts, spinning and weaving, have made enormous progress, the art of tanning has remained almost stationary for ages, the methods of the present day surpassing those in vogue centuries ago in expediting the process rather than in the quality of the product. Leather-making is simple, consisting in unhairing the skins, removing the fatty matter clinging to the membrane, soaking them in an infusion of tannin, and then softening them by means of greases.

SECTION OF EUROPEAN STURGEON SKIN (SEE P. 348).

SKIN OF DELAWARE RIVER STURGEON, TANNED IN NEWARK, N. J. (SEE P. 348).

The skins of most mammals are composed of four membranes or parts. The first is the fat-bearing tissue, situated between the flesh and the body of the skin; the second or middle portion, known as the dermis or true skin, is made up of layers of fibers interwoven and intersecting in every direction; the third or outer part is a more or less horny membrane, which contains the nerves, the smaller blood vessels, and the base of the perspiratory glands; the fourth is a thin, semitransparent cellular tissue, known as the epidermis, in which the hair is rooted. The dermis or true skin forms the leather, and the third layer above noted—the horn-like tissue containing the nerves and perspiratory glands—forms the "grain" or "bloom" of the leather. The fat-bearing tissue and epidermis, as well as the hair, are removed in the various processes of preparing the skin for tanning. In some leathers—for instance, porpoise—the grain or bloom is also removed.

Many persons in securing aquatic skins fail to appreciate the importance of care in removing them from the dead animals, and through carelessness make many knife-cuts in the membrane. In the case of furs these cuts are not so very serious, since the membrane can be sewed together and the damage concealed by the fur; but when skins are to be used for leather the cut portions are wholly valueless.

Under ordinary conditions, as soon as life ceases decomposition of the skin begins unless a detergent is applied. Salt is very generally used for this purpose and is plentifully sprinkled over the skin on its removal from the animal. Although effective, salt is not the least injurious agent that may be used, borax being generally more satisfactory and more easily removed by soaking.

On account of the great range of raw materials and requirements of the leather tride, the various processes of leather-making are necessarily numerous, differing even for skins of the same variety, according to their quality, the season of the year, and many other conditions, the correct understanding of which is the outcome of experience. However, the general principle is so far identical in all classes of leather-making that it may be outlined here.

The skins and hides usually reach the tanner after remaining in salt a greater or less length of time, depending on the distance from the place of slaughter. The first procedure is to cleanse the skins and to loosen and remove the hair and epidermis, neither of which is desired in the finished leather. In case the skins are received direct from the animals, they are easily cleansed from blood and dirt by soaking a few hours in fresh water and then washing for a few minutes in a perforated rotating drum, known as a wash-wheel, through which a stream of water is constantly flowing. If the skins have been salted, as is usually the case with aquatic pelts, a more thorough soaking and washing, with several changes of water, is necessary, the soaking sometimes extending over several days. In case of large hides which have been heavily salted the process may be assisted by a "hide-mill," in which, by means of cranks, heavy hammers are moved in pendulum fashion on the hides, or in which the hammers are alternately raised by cams. It may also be aided by using caustic soda in the tank water in the proportion of about 1 pound to each 100 gallons of water.

Various agencies are used for loosening the hair, viz, putrefactive fermentation; lime, either alone or in connection with caustic soda; calcium or sodium sulphohydrate, etc. The first is of ancient origin, and is the method even yet employed by primitive people. The green hides are permitted to remain several days in a warm, moist condition. Putrefaction soon begins, and quickly dissolves or destroys the epidermis and loosens the roots of the hairs embedded in it, when the latter easily slip out. This sweating process has little effect in splitting up the fiber bundles of the true skin and is usually employed only where a firm, solid leather is desired, as for polishing wheels, covering the Alaskan bidarkas, or more commonly in the preparation of sole leather.

A more important method of removing the hair, and the one in general use, is by means of a solution of lime or calcium oxide in water, making a milk of lime, or calcium hydrate. This not only has a solvent effect on the epidermis, but splits up the fibers of the skin, both of which are essential to the production of good, pliable leather. The skins are sunk flat and smooth in a tank or pit filled with milk of lime, and after twenty-four hours they are removed with hooks or tongs, the lime stirred up, and the skins returned, this process being repeated daily for a week or ten days, or until the hair is sufficiently loosened. The immediate effect of the lime is to swell the fibers of the skin and to split them up into their constituent fibrils, the dissolving of the epidermis being attributed to the action of the enzym products of bacteria. In preparing leather of different degrees of solidity or pliability, variations are made in the freshness and the temperature of the milk of lime, fresh lime at a low temperature being used for heavy leathers, while old lime at a high temperature is used in making thin, pliable leathers.

Comparatively few fish skins are limed, since it destroys the fiber rather than loosening it; therefore they are usually tanned without liming. Shark skins, however, will go through the lime, and eel and cat-fish skins may be limed for one or two days.

On removal from the liming tank the skin is laid, flesh side down, on a sloping beam having a convex surface, and scraped on the grain side with a blunt knife to remove the hair; then turned over and scraped on the flesh side with a sharp knife to remove all the adhering flesh, fat, and other loose tissue, this process being known as "fleshing."

Next it is necessary to remove the lime from the skin, as its presence would interfere with the subsequent tannage. Also, when soft, pliable leathers are desired, the swollen condition of the fiber produced by the lime must be reduced, and in some cases a further portion of the cementing substance of the fiber must be dissolved. Removal of the lime is sometimes accomplished by neutralizing it with an acid, as sulphuric or boracic, and then washing out the neutral salt.

A more common method, however, is by the "bran drench," either alone or supplemented by dung bates. Hot water is poured upon bran, and the mixture set with a few pailsful of a fermenting drench liquor. When the skins are placed in this liquid, maintained at a temperature of 70° F., fermentation soon ensues, floating the skins up to the surface. They are again forced mechanically down into the liquid, but soon rise as before. When this has occurred three or four times, in 12 to 16 hours, the action is generally sufficient. Large hides, especially those of alligators, are sometimes submitted to the action of paddle wheels to hasten the removal of the lime and make that removal more uniform.

This process is often preceded by treating the skin in a fermenting infusion of excrement of dogs in the preparation of lighter skins, and of pigeon or hen dung in case of heavy leathers. This not only acts on the lime so as to make it possible for it to be easily washed out, but it also renders the leather soft and pliable. The dog dung, called puer, is dissolved in water at a temperature of 90° F., and in this liquor the skins are kept in gentle motion for an hour or more. The previously plump skins become extremely soft and flaccid, and may be stretched in any direction without springing back. This operation is known as puering. The treatment with hen or pigeon bate is similar, except that it usually takes place without artificial heat and the process requires four or five days.

The hide is now a simple network of fiber, all the interfibrous substance, or filler, having been removed in the various processes above noted. Next comes the principal operation in the process of tanning, viz, dehydrating the skin and combining with it certain agencies which change the fiber network into leather. These agencies are (1) mineral salts, when the product is known as "tawed leather"; (2) oils and fats, making "chamois leather"; and (3) tannin or tannic acid, resulting in "tanned leather." Mineral salts are rarely used in tanning aquatic skins, being employed mostly in preparing laces for belts; and the chief use of the oils and fats for aquatic leathers is in preparing porpoise hides for shoelaces. Most of the aquatic leathers are prepared by the third process, the use of tannin or tannic acid.

After liming and bating, the hides are submitted to the action of infusions of tanning material. They are first worked by wheels in the tanning liquors for one to three days, according to the result desired, and then placed in tanks or pits, where, for several weeks, they are subjected to fresh tanning liquor, with frequent renewals of the liquor. On removal therefrom the skins are finished. This operation differs so much, according to the variety and quality of the skins, that accounts of the special treatment of the different kinds of skins are reserved for appropriate subchapters.

LEATHER FROM SEAL SKINS.

The seals whose skins are utilized for making leather are quite destitute of the coat of choice fur which gives to the fur-seals their great commercial prominence. Yet on account of the valuable products of leather and oil, the economic importance of this group of animals is scarcely less than that of the fur-seals. They are found in various northern waters, especially off the northern coast of Labrador and Newfoundland, in the waters of Greenland, the Arctic Ocean north of Europe, along the Nova Scotia and New England coasts, in the Northern Pacific Ocean, in the Caspian Sea, and to a much less extent in the Antarctic seas.

The principal sealing districts in the north are Newfoundland, Jan Mayen Seas, Nova Zembla, Kara Sea, and the White Sea. The Newfoundland fishery is by far the most extensive. It ranks among the most venturesome and important of all the marine industries of the world, giving direct employment to 5,000 men, while thousands of others are engaged in preparing the resultant products of leather and oil. American vessels have not engaged in this fishery except in a few instances, but the fishermen of Scotland unite with those of Newfoundland in reaping large returns from the seal hunt off the northeast coast of America.

According to Mr. Robert Badcock, the total product of seals in the Newfoundland fishery in 1901 approximated 345,000, of which 27,000 were young hoods or bluebacks, 13,000 were old hoods, 10,000 old harps, 4,000 bedlamers, and the remaining 291,000 were whitecoats or young harps. The catch of bluebacks was far greater than usual, the average take of that variety not exceeding 5,000 in one season. A small percentage of the whitecoats are known as "fast furs," the long, thick woolly or hairy covering not easily separating from the pelt, as the name implies. These are usually very young animals, less than fifteen days old. Owing to the vessels reaching the seals quickly in 1901 a larger number of fast furs were secured than usual, the total amounting to about 10,000, whereas it is usually much less. In the markets these are commonly known as wool-seal skins.

After discharge from the vessels the pelts pass through the hands of the "skinners," who remove the blubber, take out the flippers, cut off the noses, etc. The skins are at once dry-salted and placed one over the other, with the flesh side uppermost, in piles of small height. There they remain for about three weeks, when they are sufficiently cured for shipment to Europe or the United States to be tanned.

After removal of the blubber the skins of the young harp seals average 5 or 6 pounds each in weight, and are worth about 80 or 85 cents at the present time. Bedlamers' skins average about 12 pounds in weight and \$1.30 in value, and old harps, from 14 to 18 pounds in weight and 90 cents in value. The skins of the young hood or blueback seal weigh 6 or 7 pounds and sell for about \$1.35 each, and the old hoods range from 15 to 24 pounds and average about \$1.65 each in value. Of the old seals the skins of the females are preferred to those of the males, as the latter are frequently damaged about the neck and foreflippers, by the animals fighting among themselves.

The principal seal fishery of northern Europe is prosecuted in the seas about Jan Mayen and Spitzbergen by vessels sailing from Dundee and various other ports of the North Sea, and engaged also in the capture of whales and walrus. As in the case of the Newfoundland fishery, the Greenland or harp seal is the principal species secured in the Jan Mayen district, but many hooded or bladder-nosed seals are also obtained, principally by shooting. During recent years about 35 vessels have been engaged from the various ports, mostly from Norway and Scotland, and the annual take of seals has ranged between 100,000 and 200,000, the proportion of mature seals being much greater than in the Newfoundland fishery. Owing to increasing scarcity of seals north of Europe, the British vessels have almost abandoned their pursuit, leaving it in the hands of Norwegians, whose more economical outfits enable them to continue the fishery at a profit.

In the seas north of Russia, especially the White Sea and in the vicinity of Nova Zembla, many harp seals are taken in the spring by vessels from Norway and also by natives of the coast. The fishery is not so extensive as that off the Newfoundland coast, the product amounting to probably less than 20 per cent of the latter. Another important seal fishery is that of the Caspian Sea, the species captured being peculiar to those waters. This industry is centered at Astra-khan, and the annual product is reported as less than 100,000 pelts.

METHODS OF TANNING SEAL SKINS.

The total quantity of seal skins received in the markets of the world approximates 650,000 annually, valued at \$600,000. The majority are sold in London, but some are sold in Liverpool, Dundee, Hamburg, New York, Halifax, St. Petersburg, and Moscow. Most of them are tanned in Great Britain, London and Dundee being more extensively interested than any other places; but some are tanned in Norway, Russia, Germany, France, and the United States. Previous to 1901 the number tanned in the United States was small, not frequently exceeding 30,000 in any one year; but during 1901, owing to an overstocking of the trade in Great Britain, about 75,000 skins were purchased and prepared by leather manufacturers in the United States.

The general methods of tanning seal skins employed in Europe and America do not differ greatly from the treatment of similar pelts. As received at the tanneries, seal skins are thick, heavy, and extremely oily, but except in the last characteristic they closely resemble other raw skins. They are roughly cleaned of adhering flesh and blubber and as much of the oil as practicable is pressed out, when they are placed in lime pits to loosen the roots of the hair and prepare them for depi-

lation. The skins are put first into an old-lime solution and frequently changed to stronger solutions until the liming effect is completed, three or four weeks being generally required for this operation.

The action of the lime is usually hastened by frequent "handling" and changing the skins from one tank to another. When the bulbous roots of the hair are thoroughly loosened, the skins pass to the fleshing house where each one is separately laid on a beam and carefully unhaired on one side and fleshed on the other. In some establishments the skins are partly unhaired before the liming process is completed. The choicest grades of hair are used largely by plasterers, but most of it is suitable only for fertilizer or the waste heap. After a thorough washing and "striking out," currier fashion, the skins are in condition to be converted into leather.

Owing to the excessive and irregular thickness of the skins, it is desirable at this stage of the process to split or shave them, although many tanners, especially those in the United States, postpone this until the tanning is complete. The splitting is effected with a machine of clever mechanism, its principal parts consisting of two metal rollers, revolving horizontally one above the other, between which passes the skin spread out smoothly. The advance edge of the skin is presented to a keen blade, moving with great rapidity parallel with the line of contact of the rollers, thus splitting the skin into two pieces of equal superficial area, of which only the grain or outside portion is desirable for leather-making. The other half is sometimes used for making an inferior grade of leather, or cheap and somewhat deliquescent size or glue, but ordinarily it goes to the waste heap to be converted into fertilizer. The thinned skins are puered with bran or dog dung, followed by drenching and a thorough working out on a beam to remove all traces of lime salts and other refuse materials, as already described on page 331, and thus made ready for the tanning solution.

The skins are next steeped in tanks or vats containing successively stronger baths of the astringent infusion of oak bark, japonica, sumae, or any other tanning agency. For fancy shades of coloring, sumae only is used, as a rule. During the first few days the skins are frequently "handled," so that the liquor may quickly strike through them. This "handling" or "working" is cheaply effected by means of paddle wheels, which turn the skins over and over in the solution. The more they are worked by the paddle wheel, the larger the grain of the finished leather. From four to six weeks' time is usually required to complete the tanning process, even with the use of paddle wheels. In England and Scotland large quantities of the skins are tanned by sewing together two skins, flesh to flesh, around the edges, so as to form sacks or bags, which are then filled with liquid sumae. This method is cheaper and gives a better color. It is also more expeditious, requiring usually less than one week.

The tanned skins are next submitted to a sumae bath containing a

cleaning acid, such as oxalic acid or sulphuric acid, then "struck out" and lightly oiled. They are afterwards selected for coloring, and dyed if desired. To "finish" the skins, they are dampened, sammied or partly dried, and "struck out"—that is, stretched out on each side with a tool. If a bold grain be desired, in using the skins of old seals, they are embossed and dried out; but if the natural grain is retained they are blacked at once. A finish is imparted by a good bottom coat of logwood, prepared by subjecting 1 hundredweight of Campeachy hard wood and 5 pounds of carbonate of soda in 50 gallons of water until the logwood is extracted, the liquor being at once drained off.

After airing slightly in a warm place the skins are ready for "wet graining." They are again dried out in a warm place, laid away to cool, and then seasoned with three-fourths of a pint of milk and about $1\frac{1}{2}$ pints of blood added to a gallon of water, which is rubbed in well with a stiff brush. The skins are now moistened with a mixture of milk and water, in the proportion of 1 to 6, and rolled up, half a dozen skins together, grain to grain. After a few hours they are rolled, grained off, and oiled with warm cod oil, when they are ready for the market.

When carefully prepared, seal leather has greater strength and durability in proportion to its weight than almost any other on the market, and on account of its choice and attractive grain it is very popular for such articles as cardcases, pocketbooks, shopping bags, etc. Much of it is enameled for belts and upper shoe leather. The market value of seal-skin leather in the United States is from \$20 to \$30 per dozen skins, equivalent to about 50 or 60 cents per square foot.

The "fast furs" or "wool-seal" skins are blubbered in the same way as the ordinary pelts, and are sold to the fur trade in the salted state. By the fur-dressers they are washed and leathered as in the first stages of fur-seal dressing. The thickness of the pelt is reduced by shaving or by friction on an emery wheel. When the dressing is completed the hairs are dyed black or brown, scarcely any of these skins being left in the undyed state. They are used for various purposes, especially for gloves and military busbies. During some seasons they are fashionable for trimmings, and a brisk demand exists for them. This was especially the case during the early eighties, when they sold for \$3 to \$6 each, dressed. At present the average price in the dressed condition is \$1 to \$2 each. Many furriers—in America, at least—fail to recognize the fast furs as from a species of hair seals, considering them as the skins of a distinct and separate species, to which they give the name "wool-seal."

On the Continent of Europe the bluebacks are used mostly for fur trimmings after they have been dressed with the hair on; but in Great Britain and America they are usually tanned for leather purposes. During the last season some blueback skins were tanned in this country with the hair on, but they did not take very well.

LEATHER FROM SEA-LION SKINS.

Sea-lion hide was formerly considered unfit for tanning purposes, owing to its thickness and coarse texture, consequently the hunters taking these animals for oil-rendering rarely saved the skins; but at the present time the hide is worth as much as the oil. When properly tanned the skins of the young animals make a soft, velvety leather, quite popular for fancy articles. The thick hides of the old animals are used to a limited extent as a substitute for walrus hide in polishing wheels for metal-workers. It is much like bull-neck leather, and, although inferior to walrus polishing wheels, is prized by silversmiths for small work. The hides suitable for polishing purposes are onefourth to one-half inch thick, weigh 30 to 40 pounds when tanned, and are worth about 30 to 40 cents per pound wholesale. The poor or cheap hides are used to some extent as glue stock.

In preparing the skins of sea-lions for covering the Eskimo kaiaks or bidarkas, the green hides, as soon as removed from the animals, are closely rolled together and permitted to "sweat" until the hair becomes loosened, when it is readily removed by scraping with blunt knives or stone flensers. When uthaired, the moist skins are deftly sewed together in suitable patterid and stretched, flesh side out, over the boat frames, the entire structure being covered, with the exception of a circular hole or holes in the top. This boat is perfectly watertight and substantial, and, although weighing usually less than 100 pounds, will carry several hundred pools of goods in addition to the crew. Because of the softening innuonce of the water, after each day's use the boat must be hauled up out of the water, turned bottom side up and air-dried during the night. Protected in this manner and oiled occasionally, it lasts many seasons. Sea-lion skins are also used to some extent for covering the bidarrahs, which differ from the bidarkas in that they are much larger and more substantial. Usually, however, walrus hides are used for that purpose.

The natives make various other uses of sea-lion skins, such as tent coverings, harness for the sledge dogs and reindeer, and, in case of very young animals, even for clothing. When used for these purposes the hides are sweated, as when used for covering the bidarkas, then stretched for about ten days to cure, when they are taken down, rubbed between the hands to render them pliable, then cut into suitable size for use as may be desired.

In the fisheries of the southern seas, sea-lion hides were sometimes saved and brought to port. In curing them for this purpose they were removed from the animal with half an inch of blubber adhering. After washing and while yet wet they were plentifully sprinkled with salt rubbed well into the fat, particularly around the edges and neck folds, and then packed in tiers in the ship's hold.

Sea-lion skins for fancy leather are tanned in precisely the same

manner as seal skins, and especially those of large seals. The only difference in treatment is due to the greater size and body of the former. On account of the difficulty in procuring sea-lion skins free from scars and markings, and also the ease with which its peculiar grain is imitated on seal leather, the great bulk of the sea-lion leather on the market is prepared from seal skins. The value of the genuine skins when converted into leather ranges from \$2 to \$12 each, according to their quality and freedom from damage.

LEATHER FROM WALRUS SKINS.

Formerly the principal use of walrus hides in Europe was for the rigging of vessels, for which it is especially adapted. For many years nearly all the rigging of vessels on the north coast of Norway and Russia was made of this article. The skins were also employed for protecting the rigging of vessels from chafing. Later came their use in northern Europe for manufacture into harness and sole leather.

Then the thick heavy leather was adopted by silversmiths and other manufacturers of bright metal objects, for removing mars and scratches and to polish fine metal surfaces. The hide is particularly desirable for this purpose because of its peculiarly tough grain. It is usually cut into circular shape, forming a wheel of solid leather, but sometimes a ring of leather is cemented to a wooden center by which it may be attached to a revolving head or mandril. Other than that made from bull neck, buffalo, or sea-lion hides, there is no satisfactory substitute for walrus leather for these purposes. The thickest parts of the hide are the most valuable, and the demand at the present time is quite large, the principal silver works of the United States and Europe making use of it. The London value of an average hide suitable for polishing purposes is in excess of \$100.

About 30,000 pounds of tanned walrus hides are imported into the United States annually. The import value is about \$25,000 and the selling value after it is cut in the form of wheels is from \$40,000 to \$50,000. The quantity used in Europe is probably double the amount of the importations into this country. A small quantity of walrus hide has been tanned on the Pacific coast of the United States, but the quality of the output is reported as inferior to that prepared in Great Britain. As shipped from the tanneries, the "sides" weigh from 30 to 200 pounds. The cub sides weigh from 30 to 40 pounds, measure from $\frac{1}{4}$ to $\frac{1}{2}$ inch in thickness, and are worth about 30 cents per pound. The largest sides weigh 180 to 200 pounds each, are 11 to 2 inches thick, and sell for \$1 to \$1.25 per pound. The average sides weigh 80 or 90 pounds, are ¹/₅ to 1 inch thick, and sell for 60 to 70 cents per pound. Of course, when cut into circular shape these are sold at very much higher prices. The average price paid by metal-workers in this country is probably between \$1 and \$2 per pound, and for the very thick hide as much as \$5 per pound has been paid.

F. C. 1902-22

Another use to which tanned walrus hide is put is as covering for the rollers used in ginning long-staple cotton, such as Sea Island or Egyptian. This is a comparatively recent use, yet probably 6,000 pounds are consumed in the United States annually in this manner. The tanned hide is cut into thin strips and attached to the surface of the roller, entirely covering that portion that comes in contact with the cotton. It is peculiarly adapted to this use and much more satisfactory than bull-neck leather or any other material formerly employed.

Formerly the light or thin hides of walrus were little used, as they were not suitable for polishing purposes, and therefore they were of small value. But during the last few years the leather made from these thin hides has become quite fashionable for such articles as cardcases, pocketbooks, belts, etc. For this purpose the leather is split and so tanned that the grain has a remarkably smooth velvety appearance.

The process of tanning walrus hides depends on the purpose for which the finished material is designed. If intended for polishing purposes the hide should be tanned as thick and heavy as possible, with a hard, tough texture. The tanning of the heavy leather consumes from six months to one year or more when properly done. Acceleration of the process is likely to result in uneven texture, with the interior fibers imperfectly tanned. It is claimed that the best of the heavy hides are English tanned.

For thin, pliable fancy leather, the skins are tanned in precisely the same manner as seal skins, except the changes and the greater length of time due to the superior thickness of the leather. It is proper to state, however, that the greater portion, indeed possibly 90 per cent, of the so-called "walrus leather" manufactured into cardeases and other fancy articles is nothing more than seal leather with a walrus grain, which is easily given to it in the process of currying. The walrus skins are so difficult to obtain and are so frequently cut and damaged that they can not be economically used for fancy articles. The seal leather is equally durable, and when properly grained and finished the substitution can be detected by comparatively few persons.

LEATHER FROM MANATEE AND DUGONG.

For many years the market has received small quantities of curiously grained, tough, and durable leather made from hides of manatee and dugong.

The manatee is found in the shallow waters of the tropical seas on both sides of the Atlantic and in the large tributary rivers. It occurs principally among the West Indian Islands, the coasts of Brazil and Florida, and on the Senegambian coast of Africa. Owing to its gregarious and inactive habits it is easily killed. Being valuable for its oil as well as for its hides, it has been so extensively slaughtered that it is now quite scarce.

The dugong or halicore is the manatee of the Asiatic and Australian

coasts. It differs from the Atlantic manatee only slightly in outward appearance, the difference being most noticeable in the shape of the tail, which in the dugong ends in flukes instead of being spoon-shaped.

The dugong is reported as much less numerous than formerly. It attains a length of about 10 feet and is reddish brown in color, somewhat lighter than the porpoise. The hide is so thick and tough that harpoons used by the whalers are almost ineffective in its capture.

The skin of the manatee, as well as of the dugong, is hard and thick, exceeding 1 inch in places, and has comparatively few hairs on the surface. When removed and salted it is of a dark lead color. The number of skins received on the markets of Europe and America is relatively small, probably not exceeding 50 annually, most of which come from Queensland. They are tanned in the same manner as seal skins, but as they are larger and heavier more time is required.

These skins produce the most characteristic grain of all marine leathers. It is quite unlike that of the seal, walrus, or sea-lion, consisting of closely associated and irregular rows of well-defined ridges, and at intervals of about one-half or three-fourths of an inch there are peculiar indentations or pin marks surrounded by a circular ridge, the locations of the hair follicles. Unlike that of walrus and sea-lion leather, this grain is rarely imitated. Indeed, it is difficult to make a satisfactory imitation. Owing to the small quantity received, there is no regular market for this leather and no standard price. It is used almost wholly for small articles, such as cardcases, belts, and the like.

PORPOISE LEATHER.

The most abundant porpoise on the Atlantic coast is the harbor porpoise or puffing pig, which occurs from Nova Scotia to the Gulf of Mexico, ascending the rivers to the limit of the brackish water. This species is not at present an object of fishery at any point on the United States coast, although occasionally it is taken incidentally in pound-nets and seines set for food-fish. Owing to the fact that the skins are rarely free from the markings of sharks' teeth, they are not used for leather purposes to any great extent.

Of much greater economic importance is the Hatteras porpoise or bottle-nosed dolphin, which occurs in great abundance on the coasts of the United States and Europe and at times has been the object of extensive fisheries. This species also has shark markings but the skins are usually in far better condition than those of the harbor porpoise. On the North Carolina and New Jersey coasts profitable fisheries have been maintained for its capture and its utilization for leather, oil, and even for food.

Porpoise fishing has been prosecuted during the winter season since 1810 at several points on the Atlantic coast, and especially along the "Banks" of North Carolina. It was abandoned for several years following 1860 and again in 1893, the period of greatest extent being

from 1885 to 1890. During the last few years the fishery has not been prosecuted, owing to conditions in the leather market, but it appears probable that it will be reestablished at an early date.

The porpoise are dressed as soon as practicable after they are dead. The flippers and the dorsal fin are cut off and the skin and blubber cut along the middle of the back and of the abdomen from nose to flukes, and the whole peeled off in two uniform parts, the hide and blubber being removed together. The halves are laid on an inclined beam, similar to that used by curriers, and the blubber shaved off and processed for extracting the oil, while the skins are salted for the tanners. The largest catch of porpoise on the coast is reported to have been about 20,000 in 1887. The value of the green hides was about \$2 per side, and when tanned they were worth \$10 or \$12 per side.

The commercial porpoise leather of England is made from the skin of the beluga or white whale. This species attains a length of 18 feet or more, and averages perhaps 14 feet in length and 10 or 12 feet in circumference. At several places along the coast of northern Europe, and to a much less extent in the Gulf of St. Lawrence, in Hudson Bay, on the coast of Newfoundland, etc., the beluga is captured chiefly for its hide, to be used in leather-making, and also for the oil that may be rendered from the blubber. The principal fishery is prosecuted by vessels from Dundee, Scotland, and from ports of Norway and Sweden. It is estimated that the annual take is over 7,000, of which 6,000 are obtained north of Europe, leaving 1,000 as the catch in the northern part of the American continent. The value of the hide when green is about \$8 per side, and when tanned it averages probably \$25 per side.

While the skins of other cetaceans are occasionally tanned, the product is of no commercial importance. These skins are very spongy and usually have a villous or woolly surface.

TANNING PORPOISE SKINS.

According to Mr. R. G. Salomon, of Newark, N. J., to whom we are indebted for most of our information in regard to the method of tanning this leather, skins of the beluga and of the Hatteras porpoise are tanned in precisely the same manner, but the former require much longer time on account of the greater body. Both are received at the tanneries in a salted condition, and the first operation consists in cleaning out the salt by soaking them in water for two or three days, according to the state of the hides and the temperature of the water. After this soaking, they are washed thoroughly in warm water and again soaked for a day or so, and the grease worked out by hand or by machinery. They are next immersed in lime solution for a length of time depending on the condition of the hides, but usually much shorter than for cowhides. After liming they are bated and washed thoroughly to remove the lime and other impurities. The skins are now immersed in whatever tannic acid is desired. When half tanned they may be reduced to the required thickness by splitting, or this

operation may be postponed until the tanning is at an end. After the tanning is completed the nap is shaved off and the leather secured and prepared for stuffing with oils and then finished in the usual manner. The new chrome or metallic tannages seem likely to produce excellent results in porpoise tanning and will doubtless soon be adopted.

Most of the beluga skins are tanned in Dundee and Glasgow, but several small tanneries in the province of Quebec prepare this leather. Porpoise tanning in the United States has been mainly at Newark, N. J.

Leather made from porpoise hides is remarkable for its tractility; a portion one square foot in area is easily drawn out to $1\frac{1}{4}$ feet in length, losing correspondingly in width, a feature possessed by few other leathers. This makes it especially adaptable for shoemaking, for in whatever direction the foot is thrust by the weight of the body the leather will adapt itself to that shape. It is also exceedingly durable, readily outlasting two or three pairs of calfskin shoes. It has another recommendation apparent only when it is wet; then it swells up, becoming almost twice as thick as in its dry condition, and absorbs water but allows very little to penetrate it. This, added to its strength and suppleness, makes it most desirable for hunting and wet-weather boots, since it is not easily penetrated by moisture under ordinary conditions. It is sold by the pound, the price varying from \$2.25 to \$3.75 per pound, each side weighing from $1\frac{1}{2}$ to $\frac{1}{4}$ pounds. Ordinarily a pound is sufficient for about three pairs of shoes.

The skin of the beluga is among the very best for leather purposes of any obtained from either aquatic or land animals. It resembles the hide of the Hatteras porpoise in many respects, especially in having the fibers running mostly in one direction and in possessing great tractility. However, the beluga is more solid and durable than the latter. Beneath the nap it has a membrane like the "shell" on the rump of a horse, " which becomes soft and flexible in dressing and makes strong and durable leather. In comparing the tensile strength of the two, it is found that a shoestring of average size made of beluga sustains a weight of about 300 pounds, whereas one of Hatteras porpoise supports 85 to 100 pounds, and calfskin only 40 or 50 pounds. If a porpoise lace lasts three months, the life of a beluga lace subject to similar usage is said to be nearly two years. Beluga leather keeps its shape when made into shoes, whereas porpoise leather gives with the movement of the feet. Considering its great tensile strength and the large pieces obtainable, it is apparent that beluga leather is remarkably well adapted to the purpose of machinery belts. A continuous piece 60 feet long and 18 inches wide has been cut from a single skin.

a The shell in horschide is the flat muscle spread over the horse's runp from the tail to the forward point of the hips and extending down to the legs, making an oval-formed sheet about 2 feet long and 14 feet wide in the widest part. This muscle grows firmly to the grain of the skin and furnishes remarkable pulling power. When shaved clean of its sinewy matter and properly tanned, this shell makes most durable leather. The members of the equinal or horse family are said to be the only land animals possessing this membrane, but it extends nearly over the entire skin of the belaga.

Leather from the beluga is especially suitable for use as shoelaces on account of its tenacity and durability. That from the Hatteras porpoise was never much used for this purpose, owing to its unfavorable size, causing much loss in cutting. Many shoelaces made of inferior leather are sold as porpoise. The genuine can be easily distinguished by grasping it with the thumb and forefinger of each hand about onehalf inch apart and contracting or pushing it together in the direction of its length, when the contracted portion will increase about one-third in width. "The genuineness of the article is positively assured by this simple test, for no other leather has this feature." ^a

The beluga laces sell for about \$8 or \$10 per gross, while calfskin laces sell for about \$1.25 per gross. No beluga laces are made in the United States, nor is the demand for them here of importance; but many are made in Scotland for the English and continental markets.

LEATHER FROM ALLIGATOR SKINS.

Occasional attempts to utilize the coriaceous epidermis of alligators in leather manufacture have been made for one hundred years or more, but not with much success until about 1855, when this novel leather became somewhat fashionable and a considerable demand developed. The market, however, was not long continued, and after a few thousand hides had been shipped from the Gulf States the demand ended. During the civil war another raid was made upon these saurians to supply shoe material, and they were again slaughtered in thousands; but with the cessation of hostilities and the restoration of free commerce in shoe materials, the alligators were again left to repose for a period.

This rest, however, was only temporary, for about 1869 fickle fashion again called for the leather for manufacture into fancy slippers, boots. traveling bags, belts, cardcases, music rolls, etc. An immense demand was soon created for it, resulting in the slaughter of many thousands of the animals every year, giving employment to hundreds of men. The demand soon exceeded the productive capacity of our own country, and large numbers of skins were imported from Mexico and Central America. The consumption of this leather at present is greater than ever before, and owing to the large importations the market price is somewhat less than a few years ago. The output of the tanneries of the United States approximates 280,000 skins annually, worth about \$420,000. It is among the most characteristic of all aquatic leathersindeed, of all leathers-being curiously checkered in oblong divisions, known as "scales" or "bosses," separated by intersecting grooves, and varying in size and character from the rough horn-like scutes on the back to smooth pliable markings on other parts of the body, giving the skin that peculiar effect which makes it so popular for leather purposes.

There are several distinct varieties of alligator skins on the markets, the most important being the Floridian, Louisianan, and Mexican;

ALLIGATOR SKINS, UNDER-SURFACE AND HORN-BACK.

each differs from the others in certain well-defined characteristics, and owing to these differences each variety has its special uses.

The Florida skins are longer in the body—that is, from the fore legs to the hind legs—than those from Louisiana and Mexico, and consequently they are largely in demand by manufacturers of large handbags. They also have a number of so-called "buttons" or "corn marks" on the inside or under surface of an equal number of the scutes, resulting from embedded horn-like tissues in the center of those scales. These increase the difficulty in tanning the skins and detract somewhat from the appearance of the finished article, and for this reason the Florida skins are ordinarily the cheapest on the market. The farther south the skins are secured in Florida the greater the number of "corn marks," and those from the vicinity of Key West are almost valueless on this account.

The Louisiana skins differ from those of Florida in the absence of the "corn marks" above noted, and from both the Florida and Mexican skins in being more pliable and in having the scales more artistically curved and shaped. Consequently they are preferred for such small articles as cardcases and pocketbooks, and usually sell at the highest prices. Skins obtained in Mississippi and Texas are similar to those secured in Louisiana, while those from Georgia and South Carolina are similar to the Florida skins, except that the "corn markings" are not so numerous. All the Florida and Louisiana skins show greater uniformity of coloring, being of a bluish black on the upper surface and a peculiar bluish white on the under side.

In addition to an absence of the characteristics above noted, the Mexican and Central American skins are distinguished by having from 1 to 4 small dots or markings like pin holes near the caudal edge of each scale. The length of the Mexican skins varies greatly in proportion to the width, sometimes equaling that of the Florida skins. Those from the east coast of Mexico are the best, being lighter in color and with neat and attractively shaped scales. The west coast skins are yellowish in color when in the green state, and the scales are larger and not so artistically formed. The Florida and Louisian skins are almost invariably split down the back, or rather along each side of the back, so as to preserve the under side in a solid piece, but most of the Mexican skins are split down the middle of the abdomen, keeping the back intact, making what is commonly known as "horn alligator."

On all of these hides the scales or bosses are far apart, without mutual articulation or overlapping. The number of nuchal scutes is usually four large ones, forming a square, separated on the median line, with a pair of small ones on front and another pair behind; there are 17 or 18 transverse series of dorsal scutes, the broadest series containing 8 scutes.

The skins of the alligators or caymans from Brazil, Venezuela, and other South American countries are distinguished by having a much heavier or more borny covering than the foregoing. The cuticular plates on the back are articulated together, and those on the under surface are more strongly developed than in skins from Mexico or the United States. They are of very little value for leather purposes, owing to the difficulty in properly tanning them.

Of the 280,000 skins used each year in the United States probably 56 per cent are furnished by Mexico and Central America, 22 per cent by Florida, 20 per cent by Louisiana, and the remaining 2 per cent by the other Gulf States. The South American hides do not come on the market in the United States.

The quantity of alligators has greatly decreased in all the Southern States, and it seems only a question of a few years when it will be impossible to obtain the hides at a price that will justify their general employment. Thousands of the animals have been slaughtered merely for sport, no use whatever being made of them. It is estimated that the number in Florida and Louisiana at present is less than 20 per cent of what it was twenty years ago. This decrease is attributed largely to the shooting of them in wanton sport. It has been deemed necessary to legislate for the protection of alligators in some localities, especially in Florida, owing to the rapid multiplication of the cane rat which threatened ruin to many harvests. There is a strong sentiment among the hunters in Florida and Louisiana favorable to a law interdicting the killing of those measuring less than 5 feet in length.

The hide should be removed shortly after the animal is dead, for in the warm climates putrefaction ensues quickly and the value of the hide is depreciated. The operation is begun by cutting through the scaly covering longitudinally from the nose to the end of the tail, along either side of the horny ridge along the back, or in the middle of the under surface of the animal. The former is the usual method in Florida and Louisiana, while the latter is common in Mexico and in Central America. Formerly it was considered difficult to tan the horn-like back properly, but it is now prepared almost as readily as the more pliable portions, and its use is very extensive.

After making the incision above noted, a cut is made running from the longitudinal one to and along the middle of each of the legs on their upper side; or, if the back is to be saved, along the under side, extending almost to the wrists. After cutting around the jaws, the skin is peeled off in a blanket piece. Great care should be exercised to avoid careless cuts in the membrane. A very large percentage of the hides received in the market are badly damaged in this manner. These knife cuts may be scarcely noticeable in the raw skins, but when dressed are so apparent as to render quite valueless the part of the skin in which they are contained, resulting in much waste.

The hide should be salted immediately, the salt being carefully rubbed in all folds and crevices as well as over the entire inner surface of the skin, the use of coarse-grained salt being avoided. The edges along the abdomen and the parts from the legs are folded over neatly and the entire skin rolled up in a compact bundle and placed in a dry, cool place. Many hides spoil by reason of insufficient or indifferent salting, the grain side becoming so damaged that at best they are suitable only for second-class leather. After thorough curing, the salted hides are placed in boxes, barrels, or bags, and are bartered at the neighboring trading store, whence they are duly shipped to the tanneries.

The price received by the hunters for alligator hides varies from 15 cents to \$2 each, according to the length and condition of the skin, and averages probably about 90 cents. Prime hides 5 feet long, with no cuts, scale slips, or other defects, are worth about 95 cents each, in trade, when the hunter sells them at the country stores, and about \$1.10, cash, at the tanneries. Those measuring 7 feet are worth \$1.55; 6 feet, \$1.12; 4 feet, 52 cents, and 3 feet, 25 cents. Little demand exists for those under 3 feet in length.

TANNING ALLIGATOR HIDES.

The principal tanneries in the United States handling alligator hides are situated at Newark, N. J., and New York City, N. Y. Some hides are also prepared in New Orleans, Jacksonville, and in one or two of the tanneries in Massachusetts. Many are also exported to Germany and to England and there tanned. Alligator hides of all lengths, from 2 feet up, are used, but those most in demand are about 7 feet long. Hides over 10 feet in length are not much used, owing not only to their scarcity but to the hardness of the cuticular plates, making them difficult to tan properly and almost valueless for leather purposes, although some over 17 feet long have been prepared.

Formerly only the skin from the underpart and the sides of the animal was used, that from the back being so heavily armored with tough, horny plates and shields as to be of little value, except in case of very small hides. During recent years, however, a demand has existed for "horn" alligator, i. e., leather from the back of the animal, and this demand has been supplied by the importations from Mexico and Central America, a very large percentage of which are cut down the abdomen so as to preserve the back in one piece. The Louisiana and Florida skins are not cut "horn back" because they are not so flexible on the back as the Mexican.

On receipt at the tannery the hides are assorted according to their size, the small, medium, and large being treated separately on account of the difference in texture. With plenty of salt they are placed in a suitable storage room, whence they may be removed as required.

In the process of preparing for tanning, the skins are first immersed in vats of clear water, the smaller ones remaining about two days and the larger ones six days, according to the condition of the membrane. When sufficiently soaked they are immersed in a solution of lime, which should not be so strong as for depilating, and there they remain

from eight to fifteen days, according to their size and the conditions of the water and the temperature. Each day the hides are receled or removed into a stronger lime solution, great care being observed to avoid injuring the skin during this handling. The wet hides are now placed on a beam and shaved on the flesh side, all fat and superfluous flesh being removed. The bate of bran into which they next pass is made very weak, and in it the hides are gently agitated by means of a wheel, remaining there for ten to fifteen hours.

The hides are next cleaned in a wash-wheel tank and then immersed in a vat of oak bark extract, gambia, or sumae liquor of about 4° strength. Every day or so the liquor is made stronger, increasing to about 20° at the end of eighteen or twenty days. A gentle agitation of the tanning liquor during the last ten or twelve days is very beneficial, as it aids in the more thorough tanning of the skins and prevents the sediment of the liquor from settling in the creases, which is liable to rot the tender portions, especially in case of small hides. The hides are removed from the tanning liquor and suspended in the open air for samming, or partial drying and hardening, so that they may be again shaved on the flesh side to further reduce the thickness. They are returned to the tan liquor, where they are reeled for four or five days, the strength of the liquor being increased from time to time.

On removal from the tan liquor the second time, the hides are scoured with sumac water and selected for the different colors. Many are left in the natural color, yellowish brown. The popular dyed effects are black, and various shades of brown, green, yellow, red, etc. The coloring is done in a bath with wood and aniline dyes, the immersion lasting from ten to sixty minutes. The skins are next stretched out, and in most cases nailed on wide boards or frames for drying, and when thoroughly dry they are "staked" over iron beams or stakes for the purpose of making them flexible and pliable. If intended for shoes they are seasoned before staking, this consisting in stuffing them with tallow, fish oil, etc. But very few alligator hides are now prepared for shoe leather, since they are rather fancy for that purpose. After dressing them on the polishing machine, the skins are measured and stored in the warehouse or delivered to the leather manufacturers.

Although green alligator hides are sold according to length, tanned hides are sold by the width of the leather at the widest part. The price for skins of standard grade ranges from \$1 to \$1.65 per 12 inches of width. Some skins tanned and dyed in a superior manner sell for \$2 or more for single skins $2\frac{1}{2}$ feet in length. As a rule the Louisiana skins fetch the highest prices, and those from Florida the lowest.

Imitation alligator leather is now prepared in large quantities, principally from sheepskins or the buffing from cowhides. These are tanned according to the usual process, and before the skins are finished they are embossed with the characteristic alligator markings by passing them between two rollers.

SKINS OF SHARKS, RAYS, AND DOG-FISH.

The skins of sharks, rays, and dog-fish are commonly very rough and studded with numerous horny tuberculous markings or protuberances. Some have small imbricated and triangular scale-like tubercles; others unimbricated and nearly rhomboid, which in one species are ranged near each other in quincunxes, or they may be quite square, compact, and comparatively smooth on top. These protuberances are usually firmly fixed to the skin so that they are not easily separated therefrom. They are rough and hard and take a polish almost equal to stone.

These skins, like those of all cartilaginous fishes, are very durable. A peculiarity, in addition to the markings above noted, is the nonporous character. The pores that are everywhere present in the skins of most mammals, which give the natural grain in the tanned leather, are entirely indiscernible in the skins of these fish. The result is to render them almost proof against water absorption. Although by skillful tanning the fibers of seal and other skins may be plumped and the body of the membrane solidified, yet much water exposure loosens up the fiber and gradually permits absorption. Not being of a porous nature, shark skin is naturally free from this defect. But the advantage is also a disadvantage in some respects. The nonporous leather is practically airproof as well as waterproof, and that is a serious defect when its use for footwear is considered. Beyond this, the skins of sharks and similar fishes may be prepared in a very durable, noncracking leather, for which many uses may be found.

Formerly, large quantities of these skins were used for polishing wood, ivory, etc., for which they are excellent, owing to their roughness, hardness, and durability. But the great improvements made in preparing emery compositions and sandpapers have resulted in substituting them almost entirely for polishing purposes. However, a small demand yet exists for shark skins for cabinet-workers' use.

The principal uses made of the skins of sharks and allied fishes at the present time are for covering jewel boxes, desk ornaments, cardcases, sword sheaths, sword grips, and a great variety of small articles for which the tuberculous markings peculiarly adapt them. The demand for these purposes, however, is small and restricted, and each producer has to develop his own market. Comparatively few of these skins are prepared in the United States, and diligent search among the tanneries and leather stores will result in the finding of only a few skins. Many, however, are prepared in France, Turkey, and other countries of southern Europe, and also in China and Japan.

A Parisian manufacturer has made quite a reputation tanning the skin of a species of Malabar shark into morocco, and establishments in Turkey make green leather from the skin of the angel shark found in the Mediterranean Sea. The skin of the diamond shark obtained in the North Sea, and so called because of the shape of the markings or protuberances, is used to cover the sword grips of German officers, and for this purpose is not surpassed by any material obtainable. Some parts of the skin of certain varieties of sharks when dried and hardened take a polish equal to that of stone, and bear a strong resemblance to the fossil coral porites, and are much used in the manufacture of ornaments and jewelry.

In preparing them for the use of cabinet-makers, shark skins are merely cleaned and not tanned. The hard, dry skins are soaked in lukewarm water for three or four days, shaved on the flesh side to remove surplus flesh and muscular tissue, and then dried. The skins of some species of sharks are so hard that they can not be shaved. The appearance of these skins is improved by bleaching, using chloride of lime and sulphuric acid. The durability of some of them is remarkable, outwearing many sheets of sandpaper of equal area.

In tanning shark skin for leather or ornamental purposes an alum process is generally employed. Each establishment usually has its own particular method, but the general process is much the same, consisting of a preliminary soaking, liming, bating, and fleshing, and then tanning or preserving in an alum compound. The hard skins are first soaked in water four or five days, and then in limewater for two to six days, depending on the condition of the texture, temperature of water, etc. The skins are washed free of lime and bated in bran water; then shaved on the flesh side to remove all excess of flesh and the like. The alum solution in which they are immersed is composed of a pound of alum and one-fifth pound of salt to a gallon of water. The skins remain in the solution two or three days, with occasional stirring. On removal they are dried and are then ready for manufacturing.

STURGEON SKINS.

The skins of sturgeon are thick and unwieldy, and at first it might appear impossible to use them for any purpose other than glue or fertilizer stock. They are covered with rows of large prominent horny bosses, leaving space for comparatively little flexible membrane between each row. In the skin of the sturgeon common on the Pacific coast, and especially in the Columbia River, and those common in the Great Lakes and on the Atlantic coast the membrane between the rows of bosses may be tanned into a comparatively flexible and very durable leather, used as laces for mill belts and as durable as the belts themselves. But it is as ornamental leather, employed so as to display the rows of bosses, that sturgeon skins are especially desirable.

Some of these skins are remarkably attractive, particularly those from a species found on the coasts of Europe, which are distinguished by rows of small but very horny bosses, between which are numerous horny protuberances varying in form from a mere dot to beautiful, irregularly shaped bosses nearly half an inch in length. (See plate 35.)

Considerable variation exists in the methods of tanning sturgeon skins. Some varieties may be limed, while others go to pieces in a

SKIN OF WATER SNAKE.

SKIN OF BEAVER TAIL, AND JEWEL BOX COVERED THEREWITH.

lime solution. Alum and bark tannings are generally used, sometimes both together and at others first the alum and then the bark liquors. The method of tanning the skin shown in pl. 35 was as follows: This variety of skins is very oily, and half a gill of oil may be removed from the cavity beneath each of several of the bosses. The skin was soaked in lukewarm water for $2\frac{1}{2}$ days, and then beamed to remove all grease, surplus flesh, and the like. It was then immersed in a solution of 1 pound of alum and 4 ounces of salt to 1 gallon of water, where it remained about four days; then retanned in oak liquors, the strength of the liquor being increased daily. On removal from the tan liquor the skin was dried without any special finishing.

BEAVER-TAIL SKINS.

A very characteristic leather seen occasionally in the markets is made from the skin of beaver tails. This is one of the most curiously marked of all of the aquatic leathers, being entirely covered with unimbricated scale-like bosses of irregular outline, usually hexagonal, a few pentagonal, and some quadrangular, the sides in all cases being slightly curved. Each of the bosses is about a third of an inch or less in length. The tail itself is about 10 inches long and 4 or 5 inches wide, and the skin produces a piece of leather about 8 inches square. Probably not over 50 pieces of this leather go on the market in the course of a year, but it might readily be increased to 20,000 or more. It is not especially durable and is used mainly for covering small jewelry boxes and the like.

For the preparation of this leather the skin is removed by cutting an incision along the middle of the under side from the base to the end, and stripping it off in one piece. Sometimes this is done by the trappers, but more frequently the entire tails, preserved in salt, are received at the tanneries. The skin is cleared out by soaking in tepid water for a length of time ranging from two to eight days, according to its condition, and is then limed for two or three days. It is shaved on the flesh side and submitted to a japonica, sumac, or alum tanning solution for about two weeks, shaved again, and cleaned with a sumac or sulphuric acid solution, and then colored if desired.

Very tough and durable leather may be made from the skin covering the body of the beaver. Before the adoption of the present method of cutting hatters' furs the tanneries received many of the skins from which the fur had been elipped, and beaver leather was comparatively common in the markets. Among the Huron Indians, whose wants were largely supplied by the beaver, the skin was much used for belts, bags, thongs, and even tent coverings. At present, however, leather made from beaver skin is comparatively unknown, many dealers in fancy leathers never having seen any. The grain is noticeable, but not especially attractive, no more than that of pig skin.

WATER-SNAKE SKINS.

The hide fiber of water snakes is scarcely distinguishable from that of alligator, being close and compact. While its thinness and consequent lack of durability render it unsuitable for many purposes, the curious markings and the novelty make it desirable as covering for cardcases and other small articles. For this purpose the skins should be treated in such a manner as to retain their original coloring and appearance as much as possible. The market for these skins is so small that the tanning of them does not amount to an industry at any place, although probably more are prepared in France than in all other countries combined. The quantity prepared in the United States probably does not exceed 100 skins a year on an average.

In preparing these skins bark tanning is not often used, and most of the methods are secret, being the result of individual experiments. Mr. A. M. Villón gives the following process in use in some establishments in France where these skins are prepared. The skins are soaked for a long time in water containing sulphate of zine to prevent putrefaction. This requires at least ten days. They are fleshed, scraped, washed by hand, and placed in a bath made of water, 1,000 parts; borax, 10; boracic acid, 100; tartaric acid, 25; precipitated alumina, as much as liquid will dissolve. They are left in this for a day, then transferred to bath No. 2, containing water, 1,000 parts; phosphate of zine, 25; benzoate of aluminum, 25; glycerine, 50; alcohol, 20.

They are left for a day in this solution, then placed in the first bath for a day, then back in the second bath for another day, this being continued for five or six days, when the tanning is usually completed, and the skins are dried, lightly staked, and finished off.

SKINS OF GAR-FISH OR ARMORED FISH.

Among the very ornamental fish skins seen in jewelry and novelty stores, and used for covering picture frames, cases and boxes of various sorts, is that of the gar-fish or armored fish. The skin of this fish is covered with slightly imbricated and firmly attached layers of rhomboid horny cuticle. It is very hard and may be polished smooth and even, retaining an ivory-like finish. The rows of scale-like cuticle readily separate from the mass, but the rhomboid sections in each row remain firmly attached to each other. In using the skin as many rows of the sections as may be necessary are broken off, and these are bent and shaped as may be required, and firmly glued to the body of the frame or box. When the whole has been applied and thoroughly dried it is polished as desired. These skins are obtained mainly from Louisiana; only a few score are used annually.

In preparing gar-fish skins for tanning they are first soaked in lukewarm water for from two to four days and cleaned of surplus flesh. In some establishments skins of this kind are not limed, owing to their tendency toward disintegration when put through that process. If limed at all, it must be done very carefully in a weak solution. The skins are then bated in bran water for eight or ten hours and washed in lukewarm water. Next they go into the tan liquor, consisting of a solution of extract of bark, sunac, and alum. This liquor is made somewhat weak at first, and the strength is increased from day to day until the tanning is completed, usually at the end of ten or twelve days. After drying in a flat shape, the skin is ready for use.

Certain tribes of savages have used the horny cuticle of the gar-fish in making breastplates which turn a knife or spear and even a hatchet, although they are readily pierced by bullets. With such a breastplate is usually worn a helmet of the skin of porcupine-fish, which is covered with formidable spines. The helmet serves not only as a protection to the head, but also as a weapon of offense in butting.

FROG SKINS.

The skins of frogs and toads are used to a limited extent for leather purposes. Two or three factories in France pay much attention to tanning them, obtaining the raw skins from northern Africa, Brazil, and other tropical regions. Elsewhere than in France comparatively few are tanned. Occasionally tanners in the vicinity of New York City prepare a few frog skins on special orders, but no regular market exists for them, and it would probably be difficult to find 50 prepared skins in all the tanneries and leather establishments of the country. This leather is thin and very pliable. It possesses a delicate but not especially attractive grain, and is used principally for cardcases and other small fancy articles.

MISCELLANEOUS FISH SKINS.

Although fish-skin leather can not yet be considered a commercial article, successful experiments have been made in the preparation of good leather from the skins of the cod, cusk, salmon, and other species. At Gloucester, Mass., shoes and gloves have been made from cod and cusk skins. Some very serviceable gloves were made at Berlin in 1880 from the skins of these fish sent from Gloucester. The skin of the wolf-fish (*Lnarhichas*) is especially adapted to leather-making, and quantities of it have been placed on the market for cardcases, shopping-bags, and the like. In Egypt fish skins from the Red Sea are made into soles for shoes, and burbot skins have been used in Russia and Siberia to trim dresses. Eel skins have been largely used in Europe for binding books, and to a considerable extent in making whips, and have also been tanned and dyed and made into suspenders. In Tartary they are dried and oiled and used as a substitute for glass in windows.

Along the Yukon River, the Amur River, and in other northern regions as well, the skins of salmon, cod, and other fish are utilized for making various garments. They are taken from the fish in blanket

pieces and the scales carefully removed. The skins are then dried and afterwards worked with a scraper until they become pliable. When finished the membrane resembles kid in appearance and softness, but is almost as tough as parchment. They are frequently dyed brown, red, yellow, and indigo, and some of the garments are highly ornate. They are sewed together with fine thread, made also of fish skin. The American Museum of Natural History in New York has many of these garments, obtained principally from Eastern Siberia.

Bags and sacks of various kinds, with capacity varying from a pint to a bushel or two, are made from fish skins by some primitive peoples. Nelson describes one made from salmon skin and intended for storing clothing. It is neatly sewed with sinew thread and ornamented with bands of russet-colored fish skins and white parchment-like skin from the throats of seals. The bottom is oval shaped, with the seam inside. The upper border is hemmed, and through a series of rawhide loops, sewed at intervals around the top, passes a cord of the same material for use as a drawstring in closing the bag. These bags are said to be in common use from the Lower Yukon to the Lower Kuskokwim.

INTERNAL MEMBRANOUS TISSUES.

In addition to the skins, certain internal membranous tissues of several aquatic mammals are used for purposes of leather, especially among primitive peoples. Prominent among these are the throat lining, stomach, and intestines of seals, fur-seals, sea-lions, and walrus. The throat linings of all these animals may be made into gloves and similar articles.

The most important use of these membranes is for waterproof overgarments, or kamlaikas, from the intestines of pinnipeds, and especially of the sea-lion. For this purpose the intestines are distended with air, dried, and cut longitudinally, forming a long ribbon 3 or 4 inches wide. A number of these ribbons are neatly sewed together with a close seam in the pattern of a loose shirt, closed behind and before, provided with long sleeves, a hood fastened to the back of the neck for drawing over the head, and drawstrings around the wrists, neck, and bottom. These garments are very durable and are said to possess greater strength than india-rubber garments, are equally water-repellent, and are not affected by grease and oil.

Walrus intestines were used by the Alaskan Eskimo in making sails for their bidarrahs, or family boats. Although its total weight is only about 4 pounds, the sail is remarkably strong and durable.

THE COMMON NAMES OF THE BASSES AND SUN-FISHES.

By HUGH M. SMITH.

F. C. 1902-23

THE COMMON NAMES OF THE BASSES AND SUN-FISHES.

By HUGH M. SMOH.

The strictly American family of fresh-water sun-fishes and basses (*Centrarchidæ*) consists of numerous species, including some of our best-known fresh-water fishes, which are much sought by anglers and contribute largely to the food supply. The family is well represented in nearly all parts of the United States east of the Rocky Mountains, in Canada and Mexico, and one species is found in California.

Some of these fishes are known only to the ichthyologist and have no distinctive names by which the layman may designate them; others can claim only book names which have never come into use and probably never will; and others have received a large number of vernacular names, some general and some local in their application. Some of the popular designations are appropriate and distinctive, but others are misleading, inaccurate, and indefinite, and much confusion has been occasioned thereby in popular literature and in legal papers. This compilation is offered in the belief that a key to the numerous names of these fishes will be useful to fishermen, fish-culturists, and legislators. There is no intention to lay undue stress on the importance of common names; on the contrary, it is thought that the multiplicity of names here shown serves to emphasize the necessity for definiteness which can, in many instances, be secured only through the use of the technical names.

The common names are presented in two lists. In the first an effort is made to bring together, in alphabetical order, all the common names that have been applied to the sun-fishes in the United States and Canada, to show the distribution of these names, and to identify the species to which each common name is given. Practically all the names in print are recorded, together with a number of others reported by correspondents and associates, which have apparently not been printed.

The following explanations of the list are given:

1. The vernacular names are arranged in strict alphabetical order and are recorded in the various forms in which they are spelled or pronounced. The fish may be identified by its vernacular name by noting its technical name, and then, if necessary, referring to the latter in the systematic list of the members of the family.

2. The geographical distribution of the names is indicated as accurately as possible. Names used over a wide area and appearing often in print are marked "general." The absence of locality indicates either a lack of knowledge as to where the name is employed or the appearance of the name only in books.

3. Whenever practicable a reference is given to a published record of the use of the name for the species and region cited. In the case of many names this record was the first known, but for other names, whose earliest application has not been determined, it has been considered sufficient to refer to a standard work. The works are mentioned by numbers, which correspond to a full citation of titles and authors at the end of the paper.

In the case of names which have not before appeared in ichthyological literature or other writings, so far as known, the authority has been indicated by Roman numerals corresponding with those prefixed to the names of the following persons, all connected with the U. S. Fish Commission, who have furnished information: (*i*) Charles G. Atkins, (*ii*) William Barnum, (*iii*) S. P. Bartlett, (*iv*) John N. Cobb, (*v*) T. M. Cogswell, (*vi*) R. E. Coker, (*vii*) S. W. Downing, (*viii*) B. W. Evermann, (*ix*) Waldo F. Hubbard, (*x*) Alexander Jones, (*xi*) W. C. Kendall, (*vii*) E. F. Locke, (*xiii*) W. F. Roberts, (*xiv*) Hugh M. Smith, (*xv*) J. J. Stranahan, (*xvi*) John W. Titcomb, (*xvii*) S. G. Worth.

The second list comprises the scientific and approved vernacular names of the *Centrarchide*, and under each species all the common names that have been applied to it.

NOTES AND COMMENTS ON THE COMMON NAMES.

The fertile imagination of Rafinesque induced him to coin many names for the members of this family, and he is responsible for a large proportion of the book names mentioned in the list. More recent writers have, however, contributed a number of such names, as will appear from the list. In some cases, where common names are given without comment in local lists of fishes and in general works, it has not been possible to determine whether they were in actual use or simply supplied by the writers. This compilation is therefore probably subject to correction in a number of such names which could not be corroborated from other sources.

The names "sun-fish," "bream," and "perch" are applied with little discrimination to all the smaller species, more especially those of the genera *Lepomis* and *Eupomotis* in the Southern States. "Bream" is often corrupted to "brim" and "perch" to "peerch" or "pearch." The same names are also given to *Pomoxis*, *Ambloplites*, *Chænobryttus*, and *Centrarchus*, with or without qualifying words.

The name tobacco-box, which is applied to *Eupomotis gibbosus* in Maryland and Virginia, doubtless was based on a real or supposed resemblance in size, form, or color to the old-fashioned pocket receptacles for smoking and chewing tobacco. In regard to another fanciful name of this fish, "Frank Forrester" remarked that "the numerous spots on its body have procured for it the absurd name of pumpkin-seed in many States."

The two members of the genus *Pomoxis* are very similar in appearance and habits, and exist together in many waters. It is, therefore, no wonder that they bear many of the same common names, although each has some particular appellations.

"Strawberry bass and calico bass seem to be very appropriate designations for *Pomoxis sparoides* and have the additional advantage of being already generally in use in a large district." (Goode.) For *Pomoxis annularis*, crappie may be recommended.

The names "campbellite" and "newlight," which appear to have originated in Kentucky and to have spread thence to Indiana and Illinois, are said by Goode (33) to have been given to P. annularis "by the irreverent during the great Campbellite movement in the West nearly half a century ago," and Klippart (35) shows the origin of the name in Kentucky by recalling that the fish "appeared in the waters of that State simultaneously with the advent of the disciples of Rev. Alexander Campbell." These names are seldom heard nowadays, but are carried along in the books on fishes and are interesting nomenclatural relics. That they have not entirely died out, however, is shown by the fact that as late as January, 1903, the Fish Commission received from Kentucky an application for "newlights" for stocking a pond, and Dr. S. P. Bartlett, of the U.S. Fish Commission station at Quincy, Ill., reports that he has occasionally heard the name "campbellite" in that State. Klippart attaches these names to P. sparoides, but other writers have restricted them to P. annularis.

Monsieur Montpetit ("Les poissons d'eau douce du Canada") thus discusses the names crappie and crapet:

Crapet? Nothing similar exists in any French dictionary to designate a fish. I have reason to believe that the American word crappie is simply a transformation by the ear of the Canadian word crapet, which must have been applied to this fish a long time before the colonists of New England could have known it. Whether this fish took the name of crappie in the limpid waters of the Great Lakes or in the muddy waters of the mouths of the Mississippi, there is not less reason to believe that this name is only the alteration of the French word crapet which was given to it, either in Canada or Louisiana, a century and more before the English had become acquainted with it. Alt le crapet! That is an essentially Canadian expression which we have all heard from the mouth of our mother, when for some teasing trick or mischievous act she threatened us with soft and affectionate blows. Alt le crapet! Which meant: "No matter by what end he is taken, he is always bristling, ready to do us an injury—he is a crapet."

The euphonious French name sac-à-lait (bag of milk) which is heard in the lower Mississippi Valley and now apparently is applied to other centrarchids as well as to P. annularis, to which it was originally given, has been corrupted to "suckley perch" in Louisiana near New Orleans. John Demon and shad, names mentioned by Mr. Goode as being applied to the crappie, have not recently been heard, and their geographical distribution is unknown to the compiler. According to Professor Evermann, tin-mouth and paper-mouth are names now often heard in Indiana, the former having reference to the color of the inside of the mouth of the crappie, the latter to the fact that the mouth tears easily when hooked.

Of the numerous names applied to members of the genus *Micropterus*, none is so distinctive as black bass, with the qualifying terms large-mouthed and small-mouthed, and these are the designations which should be generally adopted and adhered to, even though few, if any, specimens are really black.

Mr. Goode (33) recalls that "Charlevoix, a Jesuit missionary who explored Canada in 1721, mentions a fish called *achigan*, which is thought to have been the large-mouth." M. Montpetit, in his "Les poissons d'eau douce du Canada," has adopted achigan as the most appropriate vernacular name and writes as follows regarding it:

In the province of Quebec, in more than one American State, the name achigan will persist and will perhaps finally prevail even on the continent of Europe. By priority, recognized as a principle by the naturalists of Europe and America, it has incontestable titles, since for centuries and centuries, doubtless, before Landonnière called this fish *salmoides* the aborigines of Canada designated it under the name of achigan. It is a name of terror, the Algonquin name, picked up by Charlevoix and religiously preserved among us. One savant, versed in the savage languages, the Rev. Father Lacomb, O. M. I., has claimed that the word means the fish which disputes, which struggles, which shakes and bungles the line. Those who have seen it at work will admit that that is just its description.

THE FISHERIES AND FISH TRADE OF PORTO RICO IN 1902.

By W. A. WILCOX,

Agent of the United States Fish Commission.

THE FISHERIES AND FISH TRADE OF PORTO RICO IN 1902.

By W. A. WILCOX, Agent of the United States Fish Commission.

INTRODUCTION.

During the winter of 1898–99, soon after the occupation of Porto Rico by the United States Government, an investigation of the fishery resources and fishery business of that island was made by the United States Commission of Fisheries. Four years having elapsed since the change from Spanish to United States rule, it was thought desirable to revisit the island and make a canvass of the fisheries, with special reference to the present conditions, the amount of capital invested, apparatus used, amount and value of fishery products, and number of fishermen; also the amount and value of fishery products imported during the past four years. The results of this canvass, which was made by the writer in January, February, and March, 1903, are here presented. The statistical and general information pertain to the calendar year 1902 unless otherwise stated.

For courtesies and assistance rendered acknowledgments are given to the following persons: Hon. Charles Hartzell, secretary of state; Hon. James S. Harlan, judge-advocate; Hon. John R. Garrison, auditor; Hon. A. R. Cruzen, collector of customs and deputies; F. D. Griffith, of the auditor's office; Messrs. Fritze Lundt & Co., of San Juan and Mayaguez; and the French Transatlantic Steamship Company.

IMPORTATIONS OF FISHERY PRODUCTS.

Porto Rico is divided into seven districts, the population of each, by the census of 1899, being as follows:

| Aguadilla | 99,645 |
|-----------|----------|
| Arecibo | 162,308 |
| Bayamon | 160,046 |
| Guyama | |
| Humacao | |
| Mayaguez | |
| Ponce | 203, 191 |
| - Total | 953, 243 |

The values of fishery products imported into Porto Rico during the past ten years, with the duties paid, are shown in the following table. The amounts given for 1899 to 1902 are in United States money,

F. C. 1902-24

but for 1893 to 1897 are in the fluctuating Spanish currency, which averaged in value about 60 cents on the dollar:

| Year. | Pounds. | Value. | Duty. | Year: | Pounds. | Value. | Duty. |
|--------------------------------------|--------------|---|---|---|---|--------|--|
| 1893 1894 1895 1896 1897 | 29, 128, 693 | 1,325,070 1,649,601 1,987,676 1,815,010 2,123,931 | \$87,677 94,834 122,087 117,497 139,661 | 1898 α. 1899 . 1900 . 1901 . 1902 . | $\begin{array}{c} 17,867,619\\ 11,934,589\\ 14,145,017 \end{array}$ | | \$43, 246 38, 869 80, 993 97, 914 |

a Data for 1898 are not attainable, on account of the war.

This table shows a large decrease in the importations of fishery products during the past four years. This is partly, perhaps chiefly, accounted for by the great destruction of property and loss of life caused by the hurricane of August 8, 1899. The coffee districts of the western and southern parts of the island, which are the largest consumers of imported fishery products, were the heaviest sufferers from the hurricane. Under the most favorable conditions recovery from such disaster is necessarily slow, as several years are required for the planting and maturing of coffee trees. The very low prices for coffee discouraged planters and prevented capitalists from advancing financial aid to the impoverished native coffee-planters. In the opinion of some the generally improved conditions in the island have enabled the people to buy better food, hence the decrease in importations of dried fish. Labor of all kinds, city and country, has been in steady demand at increased wages over those received under Spanish rule. With increased incomes a more varied food is said to be in demand at the expense of fish products, which for many years furnished so important a part of the diet of the natives. The decrease in fishery imports has probably been in part from both causes. As time restores the devastated sections to normal conditions, with continued prosperity, the demand for fish products may equal that of former years.

Trade conditions in receiving and handling fish products show few changes. Of the imports 90 per cent are dry fish and 10 per cent pickled, smoked, and canned. The proportion of dry fish is about 90 per cent cod, 7 per cent haddock, and 3 per cent hake. Boneless fish have been received in small shipments. Besides being more expensive, these products have usually been imperfectly cured, and are therefore not received with favor, and future shipments are not encouraged.

Canned sardines from Europe are quite largely used, the imports in 1902 being valued at \$12,094, while those from the United States amounted to only \$2,185.

All dry fish intended for this market should be thoroughly and well cured and dried. The best keeping season is said to be January, February, and March. The largest demand for dry and pickled fish is from October to February, inclusive.

Since the occupation of the island by the United States several of the custom-houses under Spanish rule have been discontinued. At

present the chief office remains at San Juan. Mr. A. R. Cruzen is collector of customs for the entire island, with branch offices in charge of deputy collectors at the following ports: Ponce, Mayagüez, Arecibo, Aguadilla, Arroyo, Humacao, and Fajardo. The fishery imports at San Juan, Ponce, and Mayagüez will be referred to in some detail. The five remaining ports of entry, with several ports of less size and note, are quite large receivers of fish, most of which is drawn from the three first-mentioned, very few goods being imported direct.

A large amount of fish donated as relief supplies for sufferers by the hurricane of 1899 was admitted duty free during 1899 and 1900.

Since July 1, 1901, all fishery products from the United States (except bonded imported fish) have been admitted free of duty, those from foreign countries being subject to the following duties:

Duties on fishery products. (Approved May 23, 1902; revised to July 1, 1902.)

Duty free: Lobsters, canned or uncanned, shrimp and other shellfish, and turtles. Dutiable: Anchovies, sardines, sprats, brislings, sardells or sardellen, packed in oil or otherwise. In bottles, jars, tin boxes or cans, containing $7\frac{1}{2}$ cubic inches or less, $1\frac{1}{2}$ cents per package; containing more than $7\frac{1}{2}$ cubic inches and no more than 21 ress, 12 cents per package, containing more than 13 cubic inches and not more than 21 cubic inches, 21 cents per package; containing more than 33 and not more than 20 cubic inches, 10 cents per package. Fish (except shellfish) in tin packages or packages containing less than one-half barrel: Herring, mackerel, salmon, and other fish, 30 per cent; caviar, 20 per cent.

| Cents per lb. | Cents per lb. |
|---|--|
| Cod, haddock, hake, and pollock: | Mackerel, fresh, pickled, or salted 1 |
| Dried, smoked, salted, or pickled, | Salmon, fresh, pickled, or salted 1 |
| fresh frozen or packed in ice $\frac{3}{4}$ | Alewives, smoked or salted 3 |
| Halibut, fresh, pickled, or salted 1 | Other fish, dried or smoked, pickled |
| Halibut, dried or smoked 3 | or salted, fresh frozen or packed in ice 3 |
| Herring, dried or smoked 3 | Fresh-water fish, not specially pro- |
| Herring, pickled or salted 1 | vided for |
| Herring, fresh 1 | Fish, skinned or boned 1 |

SAN JUAN.

San Juan, the capital city, is credited by the last census with 19.487 population, the district of San Juan having 32,048. The city is one of the leading ports of entry for fishery products, a large portion of which on arrival are at once reshipped on local steamers or by sail to the numerous scaports of the island to which they are consigned. Several commission houses are large receivers of fishery products, the business in 1902, as compared with 1897, the last year of Spanish rule, showing an increase of 567,416 pounds and a decrease in value of \$75,853, the decrease in value being chiefly due to the change from Spanish silver to United States money.

The fishery importations for 1897 and 1902, were as follows:

| Trace | 1897 | 7. | 1902. | | |
|--|------------------|----------|--|--|--|
| From— | Lbs. | Value. | Lbs. | Value. | |
| British North American provinces United States Spain France Germany. | 270,955 4,863 | | 3,328,959 2,377,801 56,380 4,850 4,572 | \$116, 178 103, 163 9, 956 865 318 | |
| Total | 5, 205, 146 | 306, 333 | 5, 772, 562 | 230, 480 | |

MAYAGÜEZ.

The city of Mayagüez ranks third, with a population of 15,187. The district of Mayagüez has a population of 127,566. This district suffered severely from the hurricane of 1899. The importations of fishery products received at this port in 1897 and 1902 were as follows:

| | 18 | 97. | 1902. | | |
|---|-------------|----------------------------|------------------------------------|--------------------------------|--|
| Country from which exported. | Lbs. | Value. | Lbs. | Value. | |
| British North American provinces United States | 270,955 | \$290,588 15,458 287 | $947,560 \\ 420,192 \\ 125 \\ 550$ | 332,418 16,199 24 132 | |
| Total | 5, 205, 146 | 306, 333 | 1, 368, 427 | 48,773 | |

Besides the direct imports here shown, quite a large amount of fishery products from the United States was received in 1902 by local steamers from San Juan.

The fishery products are handled by Fritze Lundt & Co., Morales, Gonzales & Co., Sabater & Co., and Bravo & Co. The wholesale prices of fish at the date visited, February 16, 1903, were as follows: Codfish, $5\frac{1}{4}$ cents per pound; haddock, $4\frac{1}{4}$; hake, 3; pollock, 3; split herring, \$6 per barrel; smoked herring, 20 cents a box.

Average wholesale values per pound of dry cod at Mayagüez (expressed in cents).

| Year. | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Öct. | Nov. | Dec. |
|-------|------|----------------|-----------------|------|------|-------|-------|----------------|-------|----------------|----------------|----------------|
| 1899 | 43 | 51 | 43 | 43 | 5 | 51 | 51 | 43 | 51 | $5\frac{1}{4}$ | $4\frac{1}{4}$ | 43 |
| 1900 | 48 | 48 | $-4\frac{1}{4}$ | 41 | -4 | 41 | 41. | 41 | -13 | $5\frac{1}{2}$ | 63 | 5≩ |
| 1901 | 42 | $6\frac{1}{4}$ | $6\frac{1}{2}$ | 51 | 51 | 61 | 6 | $6\frac{1}{4}$ | 61 | 5_{4}^{1} | 51 | $5\frac{1}{2}$ |
| 1902 | . δ | 53 | 5 | 5 | 43 | 43 | -13 | 43 | 51 | 6 | 41 | 5 |

Hake, haddock, and pollock meet with only a small demand; split herring in moderate request; round herring, alewives, and boneless fish are not desirable. Quite an amount of canned fishery products of various kinds is imported from Europe, sardines predominating. With the exception of canned salmon, canned fish from the United States is seldom seen.

PONCE.

In the number of inhabitants and the amount of fishery products handled the city and district of Ponce largely lead any other section of Porto Rico. The last census reports the city with 27,952, and the district 203,191 inhabitants.

The Spanish records show the total amount of fishery imports received at Ponce in 1897 as 17,289,196 pounds, of a value in Spanish silver of \$1,030,854, on which the duties amounted to \$72,332. In

1902 the total direct imports amounted to 8,377,680 pounds, valued at \$330,074 in United States money, on which the duty was \$56,008.

The imports from the United States in 1902 being admitted free accounts in part for the decrease in duties. The large decrease in direct imports in 1902 is due partly to the fact that the receipts were entered at the San Juan custom-house and forwarded from that port by local steamers, which was not the case in 1897.

The following quotations of values and notes on the market are of interest:

Feb. 10, 1903.—Total receipts of the past two weeks, 285 tierces, 79 drums, and 42 boxes of cod; 80 tierces of haddock, 8 of pollock, and 2 of hake. Last sales, cod $5\frac{1}{4}$ cents, haddock $4\frac{1}{4}$ cents, and split herring 6 per barrel.

Feb. 24.—Receipts past two weeks, 619 tierces and 100 boxes of cod, 90 tierces of haddock, 253 barrels of herring. Sales of cod 54 cents, haddock 44 cents, and split herring \$5.50 per barrel. The demand just at present for cod is anything but satisfactory, and the explanation we offer is the low prices which our planters are receiving for our Porto Rico coffee, owing to the unsatisfactory situation of this article in the world's markets, and for this reason merchants and planters in the interior are buying only what they require for immediate consumption; therefore sales of round lots, such as were formerly effected, are nowadays quite out of the question.

THE DOMESTIC FISHERIES OF PORTO RICO.

Although there are many species of excellent food-fishes native to Porto Rican waters, none of them are canned, dried, smoked, or pickled. The local demand is good, yet poorly supplied with fresh fish at high prices. Whether fish can be well cured in the trying climate of the Tropics remains to be demonstrated. If some of the fine food-fishes now found are in ample abundance after supplying the local demand, they could be sent to northern markets quicker and cheaper than is now possible with fresh fish from the Pacific coast, from which shipments are made every year in increased quantities. The profitable canning of the spiny lobster, which is quite plentiful on the south side and eastern end of Porto Rico, is also a possibility.

Oysters of good flavor and small size are quite plentiful in the lagoons and arms of the sea at several places on the south side of the island; also in the waters of San Juan Harbor. At the latter place the sea wall is covered with small oysters $\frac{1}{2}$ to $1\frac{1}{2}$ inches in length. On the south side of the island they are usually attached to the roots and lower branches of the mangrove trees at the shore. The largest of the oysters compare with 2-year-old seed of Virginia waters, but are very poor and quite salty. No oysters are planted, nor is any attention given to their improvement or cultivation. Occasionally a few are gathered and peddled at 10 cents a dozen through the streets of the eities.

The few fishermen at most of the numerous ports are satisfied with small incomes derived from a small amount of labor. Many of the men combine a little fishing with work on the plantations, lightering

of vessels, and other work. During the past few years a steady demand for labor on shore at increased wages has induced the most enterprising of the fishermen to give more time to shore work at the expense of the fisheries.

The only boats employed in the fisheries of Porto Rico are small open sail or row boats, and these are used only when the weather conditions are favorable.

The total consumption of fish-food products in Porto Rico during 1902 and the average amount per capita were as follows:

| Kind. | Lbs. | Average pounds per capita. |
|-----------------|-------------------------|-----------------------------------|
| Imported, cured | 20,503,507 2,169,770 | $21\frac{1}{2}$ $2\frac{1}{4}$ |

SAN JUAN.

The eity of San Juan is but poorly supplied with fresh fish, sold from two stalls in the eity market and to a small extent by street vendors, who carry their stock on their shoulders suspended from a pole, a small pair of scales completing the outfit. The market prices for undressed fish range from 8 to 12 cents a pound, the fishermen receiving an average of 5 cents a pound.

The local fishermen of 1902 numbered 25, having 10 small boats. Their aggregate catch amounted to 120,000 pounds, valued at \$6,000. This catch was all by hook and line and most of it from the waters of San Juan Harbor, the species being the same as those taken by the neighboring fishermen of Palo Seco, which furnishes the chief supply to the citizens of San Juan.

PALO SECO.

This small fishing village is at the mouth of Bayamon River, nearly opposite the city of San Juan and the entrance to its harbor. During 1902 the fishermen numbered 80, with some \$6,000 invested in boats and fishing gear. Their catch amounted to 280,000 pounds, valued at \$16,800. They appear satisfied with a small income which might be largely increased by working more continuously. Of the 80 fishermen, the number daily engaged in fishing is said not to average over 20. The catch is in the waters of the harbor, and, at times, by trawls, hand lines, and trolling a few miles outside of the harbor, and is marketed at San Juan. This is one of the few places where fish are sold by weight, averaging the fishermen 6 cents a pound gross. Fish are fairly abundant at all seasons.

The fishing apparatus consists of haul-scines of 125 to 150 fathoms each, drift gill-nets 150 fathoms each, trawls with 150 hooks each, and hand lines with 3 or 4 hooks each, used in deep water. Fish pots have been discontinued.

The leading species taken by the several forms of apparatus are as follows

Trolling: Spanish mackerel, king-fish, barracuda, hound-fish, gray snapper, dog snapper, schoolmaster, red grouper, Nassau grouper.

Cast-nets: Leather-jack, sardines, robalo, mullet, eels, pargo prieto, lane snapper. *Weirs:* Sardines, pargo, picuda, jurel, liza, robalo, mullet, mojarra. *Haul-seine:* Lane snapper, moon-lish, trunk-fish, toro, barracuda, hound-fish, mero, mullet, pargo prieto, balaju, robalo, leather-jack, sardines, mutton-fish, spade-fish, margate, runner, pompano, red goat, yellow goat, red snapper, dog snapper, gray snapper, schoolmaster.

Travi: Margate, yellow-tail, red snapper, dog snapper, parrot-fish, mutton-fish. Hook and line: Candil, toro, pargo prieto, yellow-tail, robalo, cabra mora, red goat, yellow goat, chopa amarilla, mero, lane snapper, cherna, margate, red snapper, dog snapper, schoolmaster.

ARECIBO.

Arecibo is located on the northwestern end of the island near the mouth of the Rio Grande. The city is credited with a population of 8,008, the district of Arecibo having 162,308. Quite a large amount of imported fish is used. The fresh-fish business is conducted by 50 fishermen who divide their time between fishing and work on the sugar plantations, an average of 25 men being engaged in fishing during the year when the conditions are favorable.

Fish are reported to be fairly abundant, yet the aggregate catch for 1902 amounted to only 75,000 pounds, which could have been greatly increased had the needed energy been shown. The catch is all disposed of locally by peddlers, who sell nearly everything by the bunch, averaging 5 cents a pound for undressed fish. A few large fish, among them the mero, are taken by hooks in deep water. These are cut up and sold for 6 to 8 cents a pound. Many cast-nets are also used. Bow hooks and lines have 2 to 4 hooks attached to short snoods, which are fastened near the end of the two long lines that are attached to the bow. These lines are as long as 150 fathoms and are fished 2 to 3 miles from shore in 50 to 150 fathoms of water during the summer; there is no hook-and-line fishing during the winter on account of rough water. These hook-and-line fishermen usually begin the day's work at 4 in the morning and leave off about noon. Fishpots are used in and near the mouth of the Rio Grande during the high waters of May, June, July, and August. Haul-seines are more or less used at all seasons, from the beaches adjoining the city.

Sardines are taken by haul-seines during June, July, and August. The greater part of the seine catch is the jurel, which are most plentiful during November, December, and January, their weight being from 1 to 20 pounds.

Candil or squirrel-fish are taken by hook and line in 50 fathoms of water, but are not plentiful. Spanish mackerel are taken by trolling and by seines at all seasons, but most plentifully during June and July. A few pompano are taken by seines. The following are taken by hook and line: Cabra mora, in 3 to 70 fathoms; cherna or red

grouper, weight 15 to 30 pounds; cabrilla, but few caught; pargo prieto, plentiful in 10 to 25 fathoms of water; toro are taken by hooks near the rocks in from 3 to 10 fathoms; mero by line with a single hook in deep water, weight 10 to 20 pounds; mullet are seined.

Small wooden box-pots are set in and near the mouth of the river, their catch being chiefly the common eel of small size. Eels are also taken with hook and line, and are sold in bunches of about $2\frac{1}{2}$ pounds at 15 cents a bunch.

Commercial fishing of the Rio Grande is of small extent, being confined to the season of high water, at which time the river is fished at the mouth and for a short distance above. A little fishing is done higher up the river by the natives for family use.

AGUADILLA.

The city of Aguadilla has a population of 6,425, the district of the same name having 99,645.

Fishing is carried on at all seasons, when the weather is favorable, by 50 fishermen, who have \$10,000 invested in boats and fishing apparatus. In 1902 the catch amounted to 160,000 pounds, valued at \$10,310. This was largely disposed of by peddlers in filling a local demand from the city and near-by sugar plantations, any surplus finding a ready market in Mayaguez. The average prices received for the common species is 6 cents per pound. Spanish mackerel, kingfish, red snapper, and a few others of the best species bring 8 to 10 cents a pound for undressed fish.

The most important apparatus is the haul-seine, 100 fathoms in length and 15 to 20 feet deep, 2 to 3 inch mesh in the wings and $\frac{3}{4}$ inch in the bunt. The seines are hauled on the beach in front of the city by 8 to 12 men. The catch is chiefly made during March and April. Of the species taken in seines, scad are the most plentiful, as high as a ton or more having been taken at a single haul. Salmonete are quite plentiful. A few Spanish mackerel of small size, 1 to 2 pounds, are taken; also a few flying robin.

Next in amount to the catch by seines is that by the bow-rigged hook and line. These are used as far as 4 miles from shore in 5 to 100 fathoms of water. Of the numerous species taken, the following are the most important: Runner, or *Caranx crysos*, very plentiful in 8 to 9 fathoms of water; catalufa and toro, plentiful in 6 to 7 fathoms; a few cabrilla or red-hind in 20 to 25 fathoms (by hook and line only); gray snapper, not plentiful; schoolmaster and red snapper, weighing from 2 to 25 pounds, are plentiful in 10 to 12 fathoms; yellow-tail of 1 to 2 pounds, plentiful in 50 fathoms (only taken by bow-hooks and lines); margate of 1 to 3 pounds, plentiful in 150 fathoms of water; moon-fish, 2 to 3 pounds, in 25 fathoms.

Fish-pots made of woven bamboo splints are used at all seasons, and are anchored without bait near the mouth of the Culebrinas River,

and up the same for about 2 miles. The native name of these fish-pots is "nasa." Of the numerous species taken in pots the following are noted: Salmonete, plentiful; lane snapper, of 14 to 2 pounds; red parrot, of 3 to 4 pounds; mud-fish or old wife, of 5 to 6 pounds, are plentiful; blue parrot, 2 pounds; spade-fish, 1 to 13 pounds; rockbeauty; palmoneta, of 3 to 6 pounds, are plentiful; mariposa, ½ to 1 pound; medico or barbero, ½ to 1 pound; old-wife (Balistes vetula), average weight 2 pounds. When sold in the market the skins of this fish are taken off and bring 2 or 3 cents a dozen, being dried and used for polishing or scouring. Spotted trunk-fish of 2 to 3 pounds are here sold for food: gobies (Dormitator maculatus) weighing + pound are taken in 4 fathoms, only by pots; spiny lobsters (Palinurus interruptus), occasionally taken in pots, are not much used by the natives. Outside the river, about 2 miles from shore, pots are fished in 5 to 6 fathoms. In the river pots are more or less fished at all seasons. Hooks and lines are also used in the river by 12 men having 6 boats. Their catch comprises the following, which are reported plentiful: Eels, big-eved herring, bony-fish, and robalo.

Trawls are set as far as 3 miles from shore in 85 fathoms, 75 hooks on each trawl, the following species being taken: A few pompano in 50 fathoms; cabra mora, plentiful in 5 to 7 fathoms near shore, in deep water some weighing over 50 pounds are reported to be taken; cherna or Nassau grouper, plentiful in 5 to 6 fathoms; red grouper in 10 fathoms; catalufa; toro, plentiful; gray snapper, scarce, taken in 25 fathoms; dog snapper, a few from 7 fathoms; schoolmaster, not plentiful, 8 fathoms; red snapper, plentiful; mutton-fish; pargo, from 1 to 10 pounds, plentiful, taken only by trawl; pluma (*Calamus bajonado*), plentiful in 25 to 30 fathoms, average weight 4 to 10 pounds, taken here only by trawls.

Cast nets are used near the shore in the surf, no boats being used. Their catch consists chiefly of sardines and mullet, which are plentiful.

Trolling hooks and lines are used as the fishermen visit and return from the offshore fishing grounds, the following species being then taken: Spanish mackerel of 5 to 10 pounds; king-fish of 20 to 30 pounds, plentiful; also bonito of 15 to 20 pounds.

MAYAGUEZ.

The large city market at Mayaguez has at most seasons a greater abundance and larger variety of fresh fish than is elsewhere found on the island, yet the supply seldom, if ever, fills the steady demand. In addition to the fish furnished by the few local fishermen, small amounts are received from Aguadilla by rail and sail, and from the few fishermen of several near-by places north and south of the city. Fish are most plentiful during the winter months, but there is more or less fishing all through the year. The one fish stall of the city market handles about 150,000 pounds of fish a year, 50,000 pounds

additional being sold through the streets by peddlers. Fresh fish, as sold in the market, average 8 to 10 cents a pound, undressed, with very small changes in prices of species or for seasons.

The market officials and fish handlers report very little, if any, change in the amount of receipts, prices, or abundance of the several species during the past four years. No record is kept of the receipts or sales, the aggregate for the year being from estimates of market officials and dealers. Of the numerous species at times found in the market, the following are the most common at all seasons: Salmonete, or red and vellow goat-fish, lane snapper, mullet, sardines, Spanish mackerel, king-fish, runner, grouper, scad, and snappers.

The following shows the catch by different forms of apparatus:

- Haul seines (chinchorro): Leather-jack, runner, barbudo, and casabe, all very plentiful; pompano, Nassau grouper, red hind, red grouper, lane snapper, and jurel.
 Trolling hook and line: Colirubia, picuda, jurel, green parrot, madregal, Spanish mackerel, and King-fish, the last two chiefly during December, January, February, and March; a few during other months.
 Pols: Runner and margate, very plentiful; corocoro, Nassau grouper, red hind, red grouper, gray snapper, dog snapper, schoolmaster, red snapper, lane snapper, pluma, squirrel-fish, scarce; spiny lobsters, of 3 to 4 pounds weight, fairly plentiful, cost weight.

Cast nets: Sardines and balaju.

- Trawl: Runner, mero cabrilla, red hind, red grouper, schoolmaster, mutton-fish, red snapper, and lane snapper.
- Randal (line with 3 to 4 snoods near its end, one hook on each snood): Runner, cabra mora, Nassau grouper, red hind, red grouper, gray snapper, dog snapper, mutton-fish, lane snapper, and pluma.

MONA ISLAND.

Mona Island, about 25 miles southwest from Mayaguez, is at times visited by fishermen from Aguadilla and Mayaguez for fish and hawksbill or tortoise-shell turtle. Fish are reported plentiful about the island, though but little fishing is done. The chief attraction for fishermen and others from more distant sections of the main island is the turtle fishery. Turtles are found during May, June, and July, but are never numerous. The hawksbill turtles weigh 25 to 75 pounds each; the shells from 5 to 10 pounds. During 1902, 700 pounds of the shells were sold at Mayaguez at an average of \$3 per pound, and the turtle meat at 6 to 7 cents a pound.

AÑASCO, SABINATA, AND ALGARROBO.

These three fishing settlements are a few miles north of Mayaguez. The amount of their fish business is small, and the species taken are the same as those taken by the fishermen of Mayaguez. This section of the island suffered much from the hurricane; many of the fishermen, having lost boats and fishing apparatus, gave up the business.

BOCA DE JOYUDA.

Eight miles south from Mayaguez a few fishermen live in a grove of cocoa palms that borders the beach. Their work is varied by fishing at times and extracting cocoa oil from the products of the trees at their doors. The men report fish fairly plentiful, and of the following species and weights, in pounds: Red grouper, 10 to 50; toro, 1; pargo, 5 to 30; dog snapper, 2 to 20; schoolmaster, 5 to 15; red snapper, 5 to 30; mutton-fish, 1 to 20; lane snapper, 1 to 4; margate-fish, 1 to 6; red parrot, 1 to 5; blue parrot, 1 to 5; rock beauty, 1 to 2; mariposa, 1; spotted trunk-fish, 1 to 5.

PORTO REAL.

This small settlement, near the southwestern end of Porto Rico, well represents the fisheries by its 30 fishermen who make it their entire business. Their catch during 1902 amounted to 175,000 pounds, all of which was sold fresh. The harbor is small and shallow but ample for their small draft boats. In this vicinity many species of food-fishes are quite plentiful, particularly during January, February, and March, at which time they are nearer land and the weather is most favorable. After March the fish draw away from the shore into deeper water, when the sea becomes too rough for the small boats.

Haul-seines were formerly used but have been discontinued. The bulk of the catch is now taken by pots that are anchored and buoyed in from 1 to 13 fathoms, no bait being used.

Pots are, as a rule, set singly, but occasionally in trawls, or a number are connected by a line. One trawl with 80 hooks is used in 7 to 8 fathoms. Trolling is chiefly carried on as the men go to and from the pots and trawls.

Fishing is done in the early hours of the day, pots and trawls being visited only once. The catch is then removed to the wells on their boats, the pots replaced, and hooks rebaited. On reaching the home harbor any fish not at once disposed of are removed to floating fish-cars and kept alive until such time as needed.

Buyers from Mayaguez visit Porto Real and purchase the bulk of the catch, paying $2\frac{1}{2}$ cents a pound; the remainder of the catch is sold locally, at the village of Cabo Rojo, and at the sugar plantations of the vicinity. From the latter 4 to 5 cents a pound is received.

Spiny lobsters are scarce and of small size, $\frac{1}{2}$ to 2 pounds each. They are taken in 10 to 15 fathoms of water and sold at the same price as the fish.

Spanish mackerel are fairly plentiful, those taken near shore averaging 1 to 3 pounds; 5 to 10 miles from shore larger sizes are found, the largest seen being 8 to 10 pounds. The mackerel and the king-fish are caught with trolling hook and line.

Hawksbill or tortoise-shell turtle are taken by hand on the beaches of Salinas and Mona Island, and by turtle gill-nets set off the same, each net having attached a wooden decoy turtle. This is said to attract the turtle and also helps buoy up the net. Turtles are reported scarce, the total catch of 1902 by the fishermen of Porto Real being 10 by hand and 12 by nets. The turtles weigh from 40 to 100 pounds each, having an average of 5 pounds of clear shell. The fishermen receive \$3 a pound for shells and 3 to 6 cents a pound for the meat of the turtles.

The fishermen keep no record of their catch by species, but report most of the several species plentiful. Very many fish too small to be marketed are caught. These are given away to the poor and nothing is wasted.

The following species are reported as being taken by the apparatus named:

Pots or nasa: Red goat, vellow goat, lane snapper, rock hind, Nassau grouper, red hind, red grouper, red snapper, gray snapper, mutton-fish, plume, loro colorado, blue parrot, candil, margate, spade-fish, rock beauty, blue angel, trunk-fish (little esteemed), lobsters (scarce).

Cast nets: Sardines, scad, chopa amarilla. Trawl (palangra): Runner, cabra mora, grouper, red hind, red grouper, gray snapper, dog snapper, schoolmaster, red snapper, mutton-fish.

Trolling: Spanish mackerel, pluma, zapatero or leather-jack, runner, schoolmaster, yellow-tail, lane snapper.

PONCE.

The district of Ponce is bordered on the south by the Caribbean Sea for some 40 miles, about half the water front of the south side of the island. The long stretch of water front back to the foothills and mountains is largely engaged in sugar culture, back of which the mountainous district is engaged in coffee and tobacco raising. The fisheries are represented by a large variety of fine food-fishes that the fishermen report as quite plentiful. No fish are dried, smoked, or pickled. Fresh fish are in demand at the several cities and villages, and at plantations, and prices are quite high. The business is apparently capable of being largely increased to the benefit of producer and consumer. The fisheries are represented, from west to east, by a few fishermen at the following places: Guanica, Guavanilla, Ponce, Isabel, and Salinas, the total being 110 men.

Guanica has 20 fishermen who dispose of their fish to a local demand and at the city of Yauco. The 14 fishermen of Guavanilla also sell at Yauco and to their own neighborhood.

Ponce has 40 men who fish more or less, about half of the number depending on the fisheries for a living; the remainder divide their time between fishing and other work on shore. Their catch is disposed of at the city market and by street peddlers.

Isabel has 22 fishermen who sell their catch near home and at Coamo by peddling.

The 14 fishermen of Salinas find a market near home and at Guayama.

The fishermen of the several places mentioned fish more or less at all seasons of the year. The catch is made in the waters of the home harbors and for 4 to 6 miles out. Fish are most plentiful near shore during January, February, and March.

Two-thirds of the catch is made by the use of pots that are anchored without bait and visited once a day.

The following species comprise the bulk of the catch by pots at the several fishing stations of the district of Ponce:

Pots: Squirrel-fish, zapatero, red goat, yellow goat, rock hind, red hind, red grouper, toro, gray snapper, red snapper, mutton-fish, yellow-tail, margate, pluma, red

parrot, blue parrot, spade-fish, rock beauty, blue angel, medico, trunk-fish. Haul seine: Runner, pompano, red hind, red grouper, lane snapper, casabe, barbudo, sardines, and Spanish mackerel.

Trolling hook and line: Spanish mackerel, king-fish, barracuda, yellow-tail, rock hind, red hind, red grouper, schoolmaster, mutton-fish, red snapper, lane snapper.

Cast-nets: Sardines, pompano, jurel, cultas-fish. Trand: Cabra mora, Nassau grouper, red hind, dog snapper, schoolmaster, red snap-per, mutton-fish, lane snapper. Hand hook and line: Madregal, red grouper, pargo prieto, dog snapper, gray snapper,

lane snapper, mutton-fish, pluma, runner, mero, Nassau grouper, red hind.

Spiny lobsters of 1 to 5 pounds each are taken in pots, but apparently are not very abundant. They are sold at same price as the fresh fish, or an average of about 4¹/₃ cents a pound.

Tortoise-shell turtles, weighing 20 to 100 pounds, are taken off the beaches of the main shore and the island of "Caja de Muertos," off the southeastern shore of Ponce, and other small islands. The catch is made by hand as the turtles come on shore to lay their eggs. Not over 400 pounds of shell are taken by the fishermen of the district.

Market fishery of Ponce.-The fisheries are represented in the large city market of Ponce by one fish stand, which poorly supplies the city demand for fresh fish. No account of the amount of sales is kept. The dealer and market official reported it as being about 200 pounds a day, or some 75,000 pounds a year. On visiting it February 20, about 200 pounds comprised the stock, which represented the following 14 species: Spanish mackerel, king-fish, runner, cabra mora, Nassau grouper, toro, margate, blue tang, medico, squirrel-fish, cabrilla, lane snapper, blue parrot, and file-fish. The fish are sold undressed, usually by the bunch instead of weight, averaging 8 to 10 cents a pound for fresh fish or spiny lobsters. A few small shell ovsters arrive from Guayanilla in old kerosene tins, the fishermen receiving 20 cents a can for them. About 4,000 pounds of crawfish annually come from Portuguese or Dangerous River. These are taken by dip nets and bring at the market 8 to 10 cents a pound. Besides the 200 pounds of fish daily sold at the market, about half as much more is sold at the playa or landing and surrounding country by peddlers.

ARROYO.

This port has a population of 2,757, a custom-house, several stores that handle considerable dry fish, most of which comes from the larger cities, with occasional direct importations. The home fisheries are represented by 60 men who follow fishing, plantation, and other work. This is about the same number of fishermen as in 1899, though they fish less, work on shore being more plentiful and attractive.

Fish are reported fairly plentiful. When engaged in fishing, men leave the port at 4 a. m., returning about 8 a. m. of the same day, and as a rule do no more fishing that day. The catch is sold from half a dozen rough tables at the shore landing in front of the village. The local demand is poorly supplied, much of the time there being no fresh fish for several days, as was the case at the time of the writer's visit.

The boats are of small size, rough and strong, home-built. Sail or row boats, even the largest and best, do not venture over 3 or 4 miles from shore. No wells are in the boats, no ice or salt is used, and the catch must be disposed of at once on landing. If the catch is larger than needed for local use, it is peddled on the sugar plantations. Sales are usually by the bunch, single fish, or strips of the largest, which are cut up, the price averaging about 6 cents a pound, all species being sold at the same price. About four months of the year are lost to the fisheries from weather that is unfavorable for the small boats used, but would not prevent a New England fisherman, with good equipment, from fishing.

Hawksbill turtles, once plentiful, are now scarce, only 30 being taken during 1902. This small catch was made during January and February, one net being used on the coral reefs, and by hand as the turtles were found on the shore.

Spiny lobsters, weighing from 1 to 3 and 4 pounds, are taken quite plentifully in pots set in about 6 fathoms of water and also on the coral reefs at night, when a torch and forked stick are used. The torch attracts the lobsters, and the forked stick pokes them out from holes and impales them when emerging; or when found on the reefs they can be picked up by hand. Lobster pots are baited with refuse fish, either fresh or spoiled, of any kind. The runner, when taken in pots, will soon kill itself if not removed; moray, both black and olive, from 2 to 40 pounds, are plentiful at all times. Over two-thirds of the fresh-fish catch is by unbaited pots anchored in 3 to 6 fathoms if near the shore, and in 8 to 15 fathoms when 2 or 3 miles from land.

The following species are taken by the apparatus named, the average weight of many species being given:

- Pols: Candil; red goat; yellow goat; zapatero, ½ to 3 pound; runner, 1 to 20 pounds; pompano, 1 to 3 pounds; cabra mora, 1 to 3 pounds; Nassau grouper, 1 to 6; cabrilla, 1 to 3; gray snapper, 1 to 6; dog snapper, 1 to 6; schoolmaster, 1 to 3; red snapper, 4 to 5; mutton-fish, 1 to 3; lane snapper, 1 to 2; yellow-tail, 1 to 2; margate, 2 to 5; boca colorado, ½ to 1; chopa amarilla, 1 pound; red parrot, 1 to 10; old wife, 1 to 6; spade-fish 2 to 10; blue angel, 1 to 5; file-fish, ½ to 6; trunk-fish (scarce); puffer (not eaten); capitan or hog-fish (4 to 20 pounds).
 Single hook and line: Cabra mora, 1 to 3 pounds; cabrilla, 3 to 30; red grouper, 20 to 50 pounds.
- Single hook and line: Cabra mora, 1 to 3 pounds; cabrilla, 3 to 30; red grouper, 20 to 50 pounds, in from 6 to 40 fathoms of water, are taken from July to October; gray snapper, 8 to 20; dog snapper, 8 to 20; schoolmaster, 5 to 20; red snapper, 10 to 20; yellow-tail, 2 to 3 pounds.
 Trolling hook and line: King-fish, 10 to 60 pounds; Spanish mackerel, 1 to 10; red grouper, 20 to 50; gray snapper, 8 to 20; pompano, 5 to 10; cabra mora, 2 to 3; Nassau grouper, 5 to 70; gray snapper; dog snapper; schoolmaster; barraeuda.
 Haul scine: Zapatero, ½ to 12 pounds; runner; pompano; Nassau grouper; multon-fish; lane snapper; robalo, ½ to 15 pounds; Spanish mackerel; mullet, 1 to 3 pounds;
- pounds.
- Cast nets: Sardines, mullet, robalo. These nets are here used only for taking bait. Gill nets: Only 2 species reported, the balaju and hound-tish. The latter, weighing 5 to 8 pounds, are plentiful, but are not sold for food.

Bow hook and line (used in 40 to 60 fathoms): Catalufa, yellow-tail.

Trawls (seldom used): Yellow-tail, red snapper, cabrilla, Nassau grouper.

JOBOS HARBOR.

This small and quite good harbor is a few miles west of Arroyo. A few fishermen operate in the near-by waters on each side of the bay. The apparatus used and species taken are similar to those previously reported from Arroyo. The catch is disposed of at the city of Guayama and the surrounding sugar plantations; at the former to dealers at an average of 5 cents a pound; when peddled out at the plantations, 8 to 12 cents a pound is received. Not much system is used in disposing of the catch, sales being by the bunch, piece, single fish, or the lot. The catch is chiefly made by pots that are used inside of the bay. Haul seines are fished occasionally, but the rough water on the outside beaches interferes with their use. The fishermen divide their time between fishing and work on the sugar plantations.

Fish are reported of an average abundance both in the bay and the outside waters. Spiny lobsters are reported quite plentiful but are little cared for. Small-sized oysters are quite plentiful in the lagoons of the vicinity but receive very little attention.

The Guamani River, that has its outlet not far from Jobos Bay, is at times fished by the inhabitants living near its banks for their own use. Eels are plentiful in the river and are taken as needed by eel pots.

HUMACAO.

The district of Humacao, at the eastern end of Porto Rico, is credited with a population of 88,501; the city of Humacao with 4,428. The latter is 5 miles inland from the playa or landing at which is located the custom-house, several stores, and a small settlement of fishermen. The waters of this region are quite well supplied with a large number of species of fine food-fishes. Dry and pickled fish are received from the dealers of San Juan, Ponce, and Mayaguez. The fishermen and dealers find a good market for all fishery products at the city of Humacao and at the numerous large sugar plantations of the vicinity. This section of the island suffered severely by the hurricane of 1899, the local fishing business being almost ruined. Many fishermen and their families lost their lives, and all lost their fishing boats and fishing gear. Sugar plantations were for the time ruined and all business paralyzed.

The fishermen receive an average of 5 cents a pound for their catch. About one-third of the time is lost from the water being too rough for their small boats. The men appear satisfied with their small earnings that give them an average of \$125 a year, an amount that could be more than doubled with more energy given to the business. Only small sailboats with 3 men each and rowboats with 2 men are used. Most of the catch is by pots that are seldom baited. Hooks lines, and nets are but little used. All fishing is near shore, the extreme distance being some 4 miles.

Spiny lobsters of 1 to 6 pounds weight are quite plentiful. They are taken by pots, and at night they are taken on coral reefs of the neighboring islands by hand, a torch and forked stick only being used.

Fish pots are anchored in 2 to 10 fathoms of water from near shore out to a distance of 4 miles.

The catch by apparatus includes the following species:

- Pots: Red goat, runner, Nassau grouper, red hind, red grouper, catalufa, gray snapper, dog snapper, candil, schoolmaster, red snapper, lane snappen, margate, pluma, boca colorado or red-mouth fish, red parrot, capitan, spiny lobster, yellow goat, rock beauty, yellow-spotted eel, old wife, spade-fish, blue parrot, mariposa, medico, trunk-fish, moray, and file-fish.
- Hook and line: Schoolmaster, pargo prieto, red grouper, red hind, rock hind, Nassau grouper, gray snapper, dog snapper, red snapper, mutton-fish, lane snapper, chopa amarilla.

Cast nets: Sardines, balaju.

Haul seine: Mutton-fish, lane snapper, pluma, trunk-fish, barracuda, mullet, balaju, Anas seme. Antronrish, nane snapper, piuma, trunk-nsn, parracuta, mullet, balaju, hound-fish, soap-fish, moray, eagle ray, Spanish mackerel (small size), king-fish of small size, zapatero, ruiner, pompano, Nassau grouper, gray snapper, dog snapper, schoolmaster, red snapper. *Trolling:* Spanish mackerel, barracuda, king-fish.

HUCARES.

This small town is 4 miles north of Humacao. A long sandy beach, bordered by cocoa and royal palms and settled by scattering homes of fishermen, connects the two ports. The total catch by the fishermen during 1902 was stated to be 80,000 pounds, consisting of the same species previously mentioned as caught by men of Humacao.

Fish are most plentiful during the winter months, and are disposed of fresh at Humacao, Hucares, and neighboring plantations. The catch is mainly by fishing pots. Two haul seines are at times used from the beach. Cast nets and hooks are also used to a limited extent.

GUAYANES.

The small harbor of Guavanes is about 8 miles south of Humacao. The river Guayanes, that is formed from several small mountain streams, enters the harbor. Near the mouth of the river a half dozen fishermen reside and use one haul seine and 20 fish pots in the fisheries. Their catch comprises the usual species of the section and finds a market in the vicinity.

FAJARDO.

The city of Fajardo, with 3,414 inhabitants, is 2 miles inland from the playa or landing, at the northeastern end of the island. This section has many natural advantages in connection with the fisheries, which in time will be more appreciated. The surrounding country is an important sugar-raising district, with numerous villages and towns, of which Fajardo is the largest. At the playa is located the customhouse, a few stores, and quite a little settlement of fishermen. The harbor contains several small islands that afford a shelter to the small boats of the fishermen. The surrounding waters are well supplied

with a large variety of fine food-fishes, much more so than at any other fishing station. The catch is all disposed of fresh; no salt or ice is used. The small amount of ice received from San Juan is sold to hotels and a few families at 5 cents a pound. Quite an amount of dry salt-cod and some pickled fish are received via San Juan from the United States and Canada. There appears to be an opening for the catch and cure of some of the local species (including the spiny lobster) that would in a measure take the place of imported fish.

Spanish mackerel and king-fish are plentiful from December to May, but especially during January and February. Albacore or frigate mackerel are found in large schools during February, March, April, and May, after which they are not seen during the remainder of the year. They weigh from 15 to 20 pounds and are taken by seines and by trolling. Red snapper are plentiful; pompano are taken weighing 1 to 10 pounds. Numerous other fine table fish, but unknown in the markets of the United States, will be found in the list of species of food-fish taken by the various appliances. The list, while not complete, comprises most of the leading species taken in these waters.

Spiny lobsters are reported as very plentiful, their weight being from 1 to 10 pounds, those taken in pots being the smaller size. The largest are found on the coral reefs and are taken at night by hand, a torch and forked stick being used. The lobsters, seeing the light, do not move, permitting themselves to be picked up by hand. When hidden in holes they are poked out with the sticks and secured. Most of the lobster eatch is secured at night by hand.

Oysters of small size and good quality are quite plentiful on the roots and lower branches of the trees bordering the lagoons near the Fajardo light-house and off Ceiba. A few oysters are taken and sold locally at about 1 cent a dozen.

Clams are found at the mouth of the Fajardo River but not used. Of the 80 men of Fajardo that follow fishing more or less about 40 give nearly half their time to the sugar plantations. The fishinggrounds being more protected from rough seas by the several islands, less time is lost from rough water than at most places. The catch is all sold fresh to fill the local demand at Fajardo and vicinity. Prices average about 3 cents a pound for all species except Spanish mackerel and king-fish, which average 5 cents a pound.

After the volcanic eruptions at Martinique quite heavy showers of ashes fell in this vicinity, after which many small-sized fishes were found dead along the beaches.

Quite an important part of the revenue of some of the fishermen is from the sale of tortoise shell from the hawksbill turtles taken by them. The turtles are taken on and near the beaches of Mona, Vieques, and Culebra islands and those of the main shore. The catch is made from November to May, when the females come ashore to deposit their eggs in the sandy beaches, when they are taken by hand; the males

F. C. 1902-25

REPORT OF COMMISSIONER OF FISH AND FISHERIES. 386

are said to remain a short distance offshore from the beach and await the return of the females; here they are taken by gill nets.

The nets are from 10 to 12 yards in length and of 10-inch square mesh, each having a wooden decoy turtle attached. Turtles taken weigh from 30 to 100 pounds, occasionally more. The average weight of shell that is saved is 51 pounds, for which the men received \$3 a pound during 1902. The total amount of shells taken in this vicinity is reported as follows: By fishermen of Fajardo, 400 pounds; Culebra Island, 800 pounds; Vieques Island, 80 pounds; a total of 1,380 pounds, most of which was disposed of at Fajardo. Turtles are reported not very plentiful, and the fishermen pursue them with little energy; having taken and sold a few pounds, they are content to remain ashore and rest so long as any money is left.

Faiardo River is to a small extent fished for the first 6 or 7 miles up from its mouth by the citizens of the vicinity. The catch is chiefly a small-sized fish known as "dajao" (Agonostomus monticola) that is taken in small seines. Land crabs are quite plentiful along and in the banks bordering the river. The natives living along the river banks take the crabs from their holes in the bank during the dry season by digging them out. During the wet season the crabs are found above ground and are then caught by hand, a torch being used.

The proportion of the catch by fishing apparatus at Fajardo is approximately five-eighths by seine, one-eighth by hook and line, and one-fourth by fish pots, but a small amount is also taken by cast nets. All boats and nets are made by the fishermen. Seines are 125 to 150 fathoms long, with a bag in the center; mesh one-half inch in the center and 11 to 2 inches in the wings. Pots are not baited, but anchored in 2 to 12 fathoms in the harbor and around the neighboring islands. The boats are small, rough, and strong, without wells; none large enough to have custom-house register. Those with sails have cat or sloop rig. The apparatus employed, with the species taken, given somewhat in the order of their importance, are as follows:

- given somewhat in the order of their importance, are as follows:
 Fish pots: Candil; red goat, plentiful; yellow goat, scarce; runner or jurel, 5 to 10 pounds (in large schools during February, March, and April); cabra mora; Nassau grouper; red hind; red grouper; toro; pargo prieto; dog snapper; schoolmaster; red snapper; mutton-fish; lane snapper; yellow-tail; margate; porgy; pluma; loro colorado; oldwife; blue parrot; spade-fish; margate; porgy; pluma; loro colorado; oldwife; blue parrot; spade-fish; margate; porgy; pluma; loro colorado; oldwife; blue parrot; spade-fish; margate; porgy; pluma; loro colorado; not 2 pounds; blue angel, 2 pounds; medico, 1 pound; trunk-fish, 1 to 4 pounds; file-fish, 3 pounds; chopa amarilla, 1 pound.
 Haut scines: Mullet, red goat, Spanish mackerel of small size, king-fish, zapatero, scad, runner, bony-fish, pompano, Nassau grouper, pargo prieto, dog snapper; schoolmaster, red snapper; mutton-fish, tarpon, lane snapper; yellow-tail, margate, porgy, pluma, chopa amarilla, blaju, and hound-fish.
 Hand lines: Candil; red goat; Spanish mackerel, 2 to 10 pounds; king-fish, 10 to 40 pounds; runner; cabra mora; Nassau grouper; red hind; toro; red grouper, 5 to 100 pounds; chopa amarilla, 1 pound; red goat, 5 to 20 pounds; schoolmaster; red snapper; mutton-fish; lane snapper; margate; yellow-tail; pluma, 2 to 8 pounds; chopa amarilla, 1 pound; red goat, 5 to 8 pounds; blue parrot, 3 to 8; trunk-fish, 1 to 4; robalo, 5 to 25 pounds; and balaju, 4 to 4 pound.
 Trolling hook and lines: Borito; hound-fish; firgate mackerel; tarpon; Spanish mackerel, 2 to 10 pounds; banana-fish, 0 to 40 pounds; mullet; big-eyed herring.

5 to 15 pounds; mullet; big-eved herring.

CEIBA.

The village of Ceiba is 5 miles south from Fajardo and 2 miles inland from the water front and fishing-camp. The 15 fishermen take three-fourths of their eatch by pots and one-fourth by cast-nets. The men divide their work between fishing and work on shore at the sugar plantations. Their eatch meets with a ready local demand.

The manatee is occasionally taken off the beach near Ceiba. A few are taken each year, usually by means of haul seines. The weight is said to run from 500 to 1,200 pounds. The flesh is highly prized and resembles beef in flavor.

LUQUILLO.

Luquillo, near the eastern end of the island, is one of the very few places on the north side of Porto Rico in which the fisheries are represented. Eight men make a small catch with pots and cast-nets. A ready home demand exists for all fish taken.

VIEQUES ISLAND.

Of the several islands belonging to Porto Rico, Vieques is the largest in size and population. It is 17 miles long by 5 miles at its greatest width, its western end being 11 miles from the eastern shore of Porto Rico. The island has several thousand population, with many quite large sugar plantations. The fisheries are represented by a few fishermen on the north and south sides of the island who find a ready local demand for their catch. Fish are plentiful in the near-by waters, yet receive but little attention, dry cod imported from far distant waters being more in demand than fresh fish taken in their own home waters.

CULEBRA ISLAND.

This island has no fishery business of importance. A few fishermen supply the few hundred inhabitants with fresh fish at times. Some fish pots are used and some attention is given to the turtle fishery, the latter furnishing 800 pounds of tortoise shells in 1902. The turtleshell catch was sold at Fajardo at \$3 per pound.

388 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

Table showing the fishermen, boats, and apparatus employed in the fisheries of Porto Rico in 1902.

List of abbreviations employed in these records.

RECORDS OF THE DREDGING AND OTHER COLLECTING STATIONS OF THE U. S. FISH COMMISSION STEAMER ALBATROSS IN 1901 AND 1902.

In 1902 the dredging, trawling, and other collecting operations of the *Albatross* were all embraced within the limits of a cruise to the Hawaiian Islands in pursuance of investigations concerning the fishes and fisheries of that archipelago. In 1901 but four stations were occupied, all on the west coast of the United States.

In the following records all stations where apparatus was employed for the purpose of collecting natural-history specimens are given dredging numbers in chronological order, and each piece of apparatus used at each station is given a separate line.

The time of a sounding is the time when the plummet strikes the bottom by the ship's local time.

The time of a net or dredge haul is the hour when such apparatus is in place or position and the actual towing or dredging commenced.

In the case of open intermediate nets the time occupied in hoisting to the surface is also noted.

Where two surface nets were used the actual time that both nets were in the water together is given as if but one piece of gear were employed.

The remarks show how many single hauls of a surface net were made at each station.

Almost invariably the dredging stations were located by soundings at each end of the line, and a majority of the dredgings were on lines of continuous development.

The drift is the direction and distance traveled over the ground in the case of bottom gear, and through the water—after getting in position—in the case of other nets. No account is taken of the distance traveled by the ship while nets are being lowered or hoisted.

"Tanner with brace" is an ordinary Tanner beam-trawl frame with a T bar joining the upper sides of the runners near the heels, thus increasing the rigidity of the whole frame. This modification was suggested by Mr. A. B. Alexander.

The "Albatross-Blake beam-trawl frame" embraces a number of improvements on the old Blake frame, suggested by Commander Chauncey Thomas, U. S. Navy, and Mr. H. C. Fassett, U. S. Fish Commission. 399

STATISTICS

OF THE

FISHERIES OF THE MIDDLE ATLANTIC STATES.

PREPARED IN THE DIVISION OF STATISTICS AND METHODS OF THE FISHERIES, UNITED STATES FISH COMMISSION.

BARTON W. EVERMANN,

Assistant in Charge.

F. C. 1902-28

STATISTICS OF THE FISHERIES OF THE MIDDLE ATLANTIC STATES,

INTRODUCTION.

The present report on the fisheries of the Middle Atlantic States is for the calendar year 1901. The statistics of the oyster fishery, however, in all sections except Long Island, New York; Delaware; Worcester County, Md., and Accomac and Northampton counties, Va., are for the oyster season of 1900–1901.

The investigation on which this report is based embraced the commercial fisheries of all the coastal waters, including coast rivers, of the various States of this region. It was begun in January and completed in October, 1902. The inquiries in the field were made by the statistical agents of the Commission as follows: Mr. C. H. Stevenson canvassed Long Island, New York; Delaware; Accomac and Northampton counties, Va., and Worcester County, Md. Mr. John N. Cobb canvassed New York, exclusive of Long Island; the Atlantic coast of New Jersey, and, in December after the regular investigation closed, obtained statistics of the smoked-fish trade of Philadelphia and additional data on the shore fisheries of Philadelphia County, Pa., and Burlington and Mercer counties, N. J. Mr. W. A. Roberts canvassed the Eastern Shore of Maryland, except Worcester and Cecil counties, and also the Patuxent River, and the Chesapeake side of St. Mary, Calvert, and part of Anne Arundel counties on the western shore of that State. Mr. John B. Wilson assisted in the work at Crisfield, Md., and canvassed New Jersey on the Delaware River and Bay from Camden to Cape May. Mr. Thomas B. Gould obtained statistics of Pennsylvania on the Delaware and Susquehanna rivers, and of New Jersev on the Delaware River above Camden. Messrs. W. A. Wilcox and T. M. Cogswell canvassed Virginia, except Accomac and Northampton counties, and also that part of Maryland bordering the Potomac River. The remaining territory in Maryland was worked by Mr. G. H. H. Moore and Mr. E. S. King, the former canvassing Cecil and Harford counties and the wholesale trade and vessel fisheries of Baltimore City, and the latter collecting statistics on the shore fisheries of Baltimore County and Baltimore City and on the vessel and shore fisheries of a part of Anne Arundel County. Messrs. Stevenson, Cobb, Roberts, Wilcox, Cogswell, and Moore obtained explanatory notes on the fisheries which are embodied in the text, and also assisted in the work of preparing

the text and compiling the statistics in the office. The general preparation and arrangement of the report was under the direction of Mr. Ansley Hall. The results of the inquiry, which in this report are presented in detail, have already been published in condensed form in Statistical Bulletin No. 131.

The fisheries of the Middle Atlantic States in 1901 ^a gave employment to 93,661 persons, of whom 70,923 were fishermen and 22,738 were shoresmen in the wholesale fishery trade, oyster canneries, and other shore industries related to the fisheries. Maryland employed in its fisheries 36,260 persons, Virginia 29,325, New Jersey 12,030, New York 11,564, Pennsylvania 2,484, and Delaware 1,998. The last general investigation of the fisheries of this group of States was for the year 1897. In connection with that canvass statistics for New York and New Jersey were also obtained for 1898. Since 1897 there has been a decrease in the number of persons employed of 3,074. There was a decrease of 6,552 persons in Maryland, 464 in New Jersey, and 394 in Delaware, but this was partly offset by an increase in each of the other States.

The total capital invested in 1901 was \$25,080,371. The investment in New York was \$9,444,271; in Maryland, \$6,506,066; in Virginia, \$3,633,104; in New Jersey, \$2,729,571; in Pennsylvania, \$2,110,162, and in Delaware, \$657,197. Compared with 1897 the investment has increased \$4,973,900, or 24.73 per cent. About half of this increase is in New York and the remainder is distributed in various amounts in all the other States, the largest percentage in any State being 61.15 per cent in Delaware.

The number of fishing and transporting vessels employed was 3,721, valued at \$3,657,103. Their net tonnage was 54,761 tons, and the value of their outfits was \$1,088,706. There has been a decrease in the vessels of 153 in number, and of 3,554 tons in tonnage, but an increase of \$339,080 in the value. The number of boats in the shore fisheries was 36,237, valued at \$2,023,880. The apparatus of capture was valued at \$1,713,454, the shore and accessory property at \$9,561,356, and the cash capital amounted to \$7,035,872.

The products of the fisheries aggregated 819,046,576 pounds, valued at \$17,485,500. New York derived from its fisheries 228,092,285 pounds, valued at \$3,894,270; New Jersey, 117,930,964 pounds, valued at \$4,755,522; Pennsylvania, 6,029,538 pounds, valued at \$251,491; Delaware, 5,835,186 pounds, valued at \$203,372; Maryland, 82,975,245 pounds, valued at \$3,767,461; and Virginia, 378,183,358 pounds, valued at \$4,613,384. The most important species in the fisheries of these States is the oyster, the yield of which was 19,749,677 bushels, valued at \$10,287,556, representing nearly 59 per cent of the total

.

 $^{^{\}rm ce}$ In the present report, it should be noted, the statistics for New York and Pennsylvania do not include the lisheries of the Great Lakes and other interior waters within the boundaries of these States.

value of products for the entire region. The yield of shad, which is next in importance, was 31,897,687 pounds, valued at \$1,253,622. The catch of clams, hard and soft, was 1,118,777 bushels, valued at \$1,074,834. Some of the other prominent species were alewives, 33,198,605 pounds, \$243,340; blue-fish, 16,317,795 pounds, \$758,122; menhaden, 493,936,462 pounds, \$987,228; squetcague, 23,496,383 pounds, \$558,653; crabs, hard and soft, 70,951,965 in number, \$495,385. The catch of alewives, blue-fish, croakers, king-fish, yellow perch, pike and pickerel, scup, shad, striped bass, and oysters, as compared with 1897, has decreased in quantity, but increased in value. In the meantime there has been an increase in both the quantity and value of a large number of other species.

The products since 1897 have increased 224,874,366 pounds, or 37.84 per cent in quantity, and \$3,161,037 or 22.06 per cent in value. There has been an increase in quantity in all the States except Delaware and Maryland, and in value in all except Delaware and Pennsylvania. The decrease in Delaware, which was 32.52 per cent in quantity and 19.34 per cent in value, is explained principally by a falling off in the catch of sturgeon, squeteague, and alewives. In Maryland the decrease in the vield of alewives, shad, and oysters has been largely instrumental in overbalancing the increase in other species. In New York the products have increased 108.19 per cent in quantity and 14.82 per cent in value. This is attributable mainly to the fact that since the consolidation of a number of the principal menhaden plants on the Atlantic coast in 1898, a considerable part of the menhaden catch formerly included in the products of other States has been credited to New York, where the home office of the company representing the combined interests is located. Therefore if the comparison is made with 1898 instead of with 1897 the increase is reduced to 8.35 per cent in quantity and 9.85 per cent in value. The next greatest increase is in New Jersey and Virginia, where it relates to a number of species. In Virginia, however, the products have been affected in quantity chiefly by the increased catch of menhaden, which has risen from 178,656,362 pounds, valued at \$255,241, to 273,493,799 pounds, valued at \$433,109. The oyster yield in this State has also increased from 7.023.848 bushels, valued at \$2,041,683, to 7,885,447 bushels, valued at \$2.923.456.

In connection with the fisheries of the Middle Atlantic States, one of the most important occurrences during the past few years is the adoption of gasoline and naphtha engines as an auxiliary means of propelling sailing vessels and boats. In New York and New Jersey these engines are used on a large number of boats in the oyster, clam, shad, and pound-net fisheries, and on many of the vessels engaged in transporting fishery products to market.

438 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

The following tables present the number of persons employed, the amount of capital invested, and the quantity and value of the products of the fisheries of the Middle Atlantic States in 1901, and also a comparison of the extent of the fisheries in 1897 and 1901:

Table showing the number of persons engaged in the fisheries of the Middle Atlantic States in 1901.

FISHERIES OF NEW YORK.

Considering the value of the fishery product, New York now ranks second among the Middle Atlantic States, being surpassed only by New Jersey. The returns for 1901 show about 10 per cent increase over those for 1898, the total value amounting to \$3,545,189 in 1898, and \$3,894,270 in 1901.

The oyster industry yields about 50 per cent of the value of the fisheries of New York, the product in 1901 amounting to 1,768,703 bushels of market oysters and 544,075 bushels of seed oysters to be replanted, the whole worth \$1,972,540. This industry is now almost wholly dependent on the growing of oysters on private areas, which a few years ago were entirely barren and unproductive. In the same year, the natural oyster reefs, to which the public resorted, yielded only 5,480 bushels of market oysters and 33,890 bushels of seed oysters, with a valuation of \$20,104, or little more than 1 per cent of the total oyster product of the State.

One of the most interesting of the recent developments in the oyster industry of New York is the extensive planting of seed oysters at the eastern end of Long Island, especially in the vicinity of Greenport and Southold. This began ten years ago, and at present about 350,000 bushels are planted annually, the seed being obtained from Long Island Sound. The oysters in those waters grow very rapidly, but, not fattening readily, they are usually taken up within a year and again planted in Great South Bay and elsewhere.

An offset to the development of oyster-planting in Peconic Bay is the decrease in this industry in Shinnecock Bay, on the south side of Long Island. In 1898 the private areas in that bay yielded 43,000 bushels of oysters, worth about \$1 per bushel; but, owing to the failure on the part of the town authorities to secure the planters in their holdings of ground, the planting has almost ceased. In 1901 less than 2,000 bushels were taken from private areas and no seed was planted.

A new departure in the fishery industries of New York, and one which gives promise of extensive development, is the cultivation of hard clams or quahogs. During the last three or four years many thousands of bushels of small clams have been bedded on private areas on the south side of Long Island. Comparatively few of these were marketed previous to 1901; in that year 9,260 bushels were sold for \$25,565. The increasing scarcity of clams on the public areas and the high market price which now prevails indicate that the cultivation of this mollusk will be greatly extended. The popularity of small clams is constantly increasing in the markets, and in time their cultivation on the south side of Long Island may even rival oyster-culture.

During the year covered by these returns, the scallop fishery at the eastern end of Long Island was in a prosperous condition, yielding 169,294 bushels, which sold for \$100,607. In 1898 the yield was 103,063 bushels, worth \$49,960; and in 1891, 69,565 bushels, worth \$48,340. This mollusk is taken entirely by means of light dredges, which are usually operated from sailboats, but to a very small extent from rowboats.

The blue-fish now ranks first in value among the food-fishes of New York State, the yield in 1901 being 9,350,502 pounds, worth \$473,366. These were taken principally by line fishermen sailing from New York City. 617 men and 48 vessels engaging in this fishery in 1901, and to a less extent in gill nets, seines, and pound nets operated along the Long Island coast. Compared with 1898, it appears that there has been a decrease in the quantity of blue-fish taken and an increase in value, the yield in 1898 being 11,214,433 pounds, worth \$387,167. The catch in 1891 was reported at 5,506,575 pounds, worth \$237,010; and in 1880 at 3,000,000 pounds, worth \$67,500. These figures furnish an illustration of the increase in value of food-fish during the last twenty-three years. Thus it appears that in 1880 the value of bluefish was 2.25 cents per pound; in 1891, 4.30 cents; in 1898, 3.45 cents; and in 1901, 5.07 cents per pound. The demand for blue-fish in the food markets is constantly increasing. To secure early supplies, a part of the fleet now leaves port in March, going southward as far as Cape Fear, and the season extends until late in November.

The yield of menhaden in New York is second only to that in Virginia, 300,682,545 being secured in 1901. Of these, 233,667 were landed at oil and fertilizer factories in Maine, 25,703,000 in Rhode Island, 154,102,335 in Delaware, and 33,118,338 in Texas, as they were caught in those respective localities. Thirty-two steamers, valued at \$459,350, including their seines and outfit, and 3 sail vessels engaged in this fishery, employing 745 men. In addition to these 191 men were employed in rendering the fish into oil and fertilizer at the factories in the State, these factories representing an investment of \$558,500.

444 REPORT OF COMMISSIONER OF FISH AND FISHERIES.

Exclusive of the oyster and clam industries and the taking of bluefish and menhaden, the use of pound nets is the most important fishery in New York. The pound nets are set principally at the eastern end of Long Island, and to a much less extent at the western end of Great South Bay and off Gravesend. This fishery was more valuable in 1901 than ever before, the 248 nets yielding 8,769,082 pounds of fish, worth \$164,557. In 1898 the yield was valued at \$108,939, and in 1891 at \$125,719. The large increase in 1901 was due principally to the higher prices prevailing in the markets. The principal species taken in pound nets are squeteague, butter-fish, flounders, and scup.

The shad yield in New York in 1901 shows a gratifying increase over 1898; indeed, it was greater than for any previous year for which returns are available since 1888. The number captured in 1901 was 888,240, valued at \$110,682. In 1898 the catch was 488,611; in 1897, 506,273; in 1896, 542,814; and in 1891, 762,946. Most of the shad are taken in Hudson River, and especially in Dutchess, Ulster, Westchester, and Columbia counties.

The sturgeon fishery shows a remarkable falling off, the value of the product decreasing from \$46,573 in 1898 to \$8,323 in 1901. This fish is now very scarce, not only in Hudson River, but also along the south side of Long Island, where it was secured in abundance six years ago. A large percentage of the sturgeon taken in Hudson River are small—under 20 pounds in weight—and are known locally as "peelicans." In 1892 the State interdicted the capture of these small fish, and this is expected to have a beneficial effect on the abundance of mature sturgeon.

The catch of sturgeon on the south side of Long Island furnishes an instance of the development and decline of coastal fisheries. The fish are taken by means of floating gill nets with 12 or 14-inch mesh, operated during May and June, and also to a limited extent in September. The nets are set 1 or 2 miles from the shore from Blue Point to Montauk Point, and especially off Amagansett, Wainscott, and Westhampton. This fishery began in 1892. In 1896 there were 103 men employed, using 37 boats and 223 gill nets, and the catch of sturgeon amounted to 314,430 pounds, gross weight, worth \$15,125. In 1898, when the fishery probably reached its greatest development, 187 men used 70 boats and 454 nets, and the gross weight of sturgeon secured was 509,365 pounds, worth \$43,864. Notwithstanding a large increase in the quantity of twine used by each boat, the average catch of fish in succeeding years showed a great decrease, and in 1901 the 57 men, using 25 boats and 257 nets, secured only 65,130 pounds, gross weight, of sturgeon, worth \$4,801. This fishery is so unprofitable at present that it promises to become extinct in a few years.

The returns for most of the minor species of fish show a considerable increase during the last five years, a result doubtless of the high cost of meats. Especially is this true of eels, which are generally distributed throughout the waters of New York. The yield in 1898 was 396,945 pounds, worth \$27,517, and in 1901 it was 722,859 pounds, worth \$50,033. In the same time the yield of flounders increased from 876,683 pounds, worth \$28,455, to 1.274,308 pounds, worth \$49,949.

The high market value of lobsters during recent years has resulted in great activity in their capture in the coastal waters of New York, as well as on other portions of the Atlantic coast; but the catch has declined from 381,020 pounds in 1897 and 332,378 pounds in 1898 to 183,539 pounds in 1901. The average catch per pot in 1897 was 81 pounds; in 1898, 59 pounds, and in 1901, 37 pounds. This decrease occurred although the number of months in which the lobster fishery is prosecuted has increased somewhat.

Probably the most noteworthy change in the methods of the fisheries of New York is the extensive adoption of auxiliary power in the vessels and boats, which makes the work to a large extent independent of weather conditions. Especially is this the case in oyster-culture and in the pound-net fisheries. Gasoline and naphtha engines are the popular forms adopted. These were introduced about ten years ago. In 1901 35 boats, worth \$30,720, and 55 vessels, worth \$176,900, were thus equipped.

The following tables show the number of persons employed, the amount of capital invested, and the quantity and value of the products of the fisheries of New York in 1901:

STATISTICS OF THE FISHERIES BY COUNTIES.

In comparing the returns by counties for 1901 with those for 1898 and previous years, a large decrease in the fisheries of Queens County is apparent. This is due to the formation of a new county, Nassau, within the former limits of Queens County, and Queens and Nassau counties combined now represent the Queens County of previous years. Also there appears an extension of the fisheries of New York County and a corresponding decrease in Westchester County, owing to a change in the boundary lines.

The extent of the fisheries in each county of New York in 1901 is shown in detail in the following tables:

| Counties. | On vessels fishing. | On vessels trans- porting. | In shore or boat fisheries | "toresmen. | Total, |
|------------------------------|------------------------|----------------------------------|---|------------|--|
| Albany | | | $ \begin{array}{r} 132 \\ 266 \\ 299 \end{array} $ | 4 | $ \begin{array}{r} 132 \\ 270 \\ 299 \end{array} $ |

a 3,432,472 pounds.

THE PRODUCTS, BY APPARATUS.

The products of the vessel fisheries aggregated 199,925,663 pounds, valued at \$2,240,582, and those of the shore fisheries 28,166,622 pounds, valued at \$1,653,688. The yield of seines was 177,736,396 pounds, \$538,351; gill nets, 6,235,399 pounds, \$151,533; pound nets, 8,769,082 pounds, \$164,557; fyke nets, 939,182 pounds, \$41,884; lines, 10,963,390 pounds, \$525,139; dip nets, 48,691 pounds, \$2,299; lobster pots, 183,539 pounds, \$21,742; eel pots, 486,158 pounds, \$333,435; spears, 180,960 pounds, \$12,192; and of dredges, tongs, rakes, etc., 22,549,488 pounds, \$2,403,138.

The following tables present, by apparatus of capture, the products of the fisheries of New York in 1901:

FISHERIES OF NEW JERSEY.

New Jersey is very favorably situated for carrying on extensive commercial fisheries, and, as all parts of the State have easy rail communication with New York, Brooklyn, Philadelphia, Jersey City, Newark, Camden, Trenton, and the immense population of the States of New York, New Jersey, and Pennsylvania outside of the abovenamed cities, the fishermen have a constant and ready market for their cateh.

As New Jersey fronts on New York and Delaware bays, the Hudson and Delaware rivers, and the ocean, both salt and fresh water species are taken, and fishing is carried on throughout the year in at least some part of the State. In the spring many of the fishermen along the coast and in the interior resort to the Delaware and Hudson rivers and participate in the shad fishery, after the close of which some of the river fishermen engage in salt-water fishing along the coast.

An important feature of the fisheries is the increasing number of sailing vessels and boats fitted with gasoline and naphtha engines as an auxiliary means of propelling them. This applies not only to the vessels used by clam buyers and clam and fish transporters, but many boats under 5 tons burden used in the clam, shad, oyster, and poundnet fisheries are so fitted, giving much greater facility in carrying on fishing operations in variable weather.

The increasing use of steamers in dredging oysters from the planted beds in Monmouth County is a noticeable feature of the industry. Formerly this work was done by sailing vessels owned by the planters, but lately they have been using these vessels merely in the preliminary thinning out of the beds or carrying oysters to market, while steamers are hired to dredge the main body of market oysters. By operating in this manner but few steamers and men are needed to do the work which formerly required a much larger number of sailing vessels and men to perform.

A point in connection with the pound-net fisheries which is not shown clearly in the tables is that for every net set in the water the owner has a duplicate on shore. As the net after being fished for several days must be brought ashore to be cleaned and repaired, the fishermen have the duplicate net to put in its place, thus avoiding any loss of time in fishing. The value of these duplicate nets has been included in the general value of the pound nets, but not the number.

During the past ten years the "stop net" has been much used, principally in catching German carp. This is a long, fine-meshed net, which is stretched across the mouth of a small creek or bight at high tide, preventing the escape of the fish when the tide turns. As the tide recedes the ground is left bare, and the fishermen walk along the inner side of the net and pick up such fish as they want. Unfortunately this net does considerable damage, as the mesh is so fine that but few fish can go through, and many too small to be of any value to the fishermen are left upon the mud to die.

Bag nets, which are used only in Burlington and Atlantic counties, principally on the Mullica River, are large, bag-shaped nets and are operated under the ice. Holes are cut in the ice, through which the net is lowered by means of ropes attached to it at each side of its entrance, and the tide sweeping in fills it out and keeps it extended its entire length. When the tide turns the net is lifted out of the water, emptied, and fished the reverse way if the fisherman desires.

German carp. — The catch of this species in 1889 was 2,725 pounds, valued at \$218, while in 1897 785,409 pounds, worth \$39,370, were taken. Since 1897 the catch has been steadily declining, amounting in 1898 to 245,983 pounds, valued at \$13,884, and in 1901 to 227,419 pounds, worth \$14,290. As a result of the good prices realized this fishery will probably be prosecuted with greater activity in the future.

Shad.—The shad season of 1901 was good in nearly all parts of the State, and all but six of the counties show an increase over the figures for 1898. The decreases in these counties are insignificant, while the increases in the other counties are important. In 1898 the catch numbered 2,749,723, valued at \$293,173, while in 1901 the number was 3,243,142, which sold for \$475,202, an increase for 1901 over 1898 of 493,419 shad and \$182,029. The greater part are taken on the Delaware River and Bay, and the remainder comes chiefly from the Hudson River and New York Bay. A few are caught along the coast, principally in pound nets.

The following shows the number taken in each county of the State:

| Table showing the | number of shad | taken in each | county of New . | Jersey in 1901. |
|-------------------|----------------|---------------|-----------------|-----------------|
|-------------------|----------------|---------------|-----------------|-----------------|

| Counties. | No. | Value. | Counties. | No. | Value. |

Sturgeon.—The sturgeon fishery of New Jersey is prosecuted chiefly in the Delaware River and Bay, a small percentage of the catch being taken in the occan. This fishery was at one time very extensive, but is rapidly declining; the fishermen are growing fewer in number each year, and as the season of 1902 was less favorable than that of 1901 it is probable that few persons will engage in the fishery in 1903. A gill-net fishery for sturgeon in the ocean off Holly Beach has been in operation for several seasons with fair success.

Efforts have been made in recent years to propagate sturgeon in the Delaware, but on account of the difficulty in securing a sufficient quantity of ripe spawn very little has been accomplished.

The following table shows the quantity and value of sturgeon, including caviar, taken in New Jersey in various years since 1890:

| Year. | Lbs. | Value. |
|---|--|---|
| 1890 1891 1892 1893 1894 1897 1898 1901 | $\begin{array}{c} 3, 635, 350\\ 3, 520, 370\\ 3, 187, 342\\ 1, 013, 604\\ 868, 326\\ 188, 027 \end{array}$ | \$90, 085 86, 419 64, 982 94, 056 100, 966 19, 352 |

Oysters.—Since the last general canvass of this State a number of changes have occurred in the oyster industry. For many years the planters had been striving earnestly for State control of the industry, and in 1899 success crowned their efforts so far as the Delaware Bay was concerned. Under the provisions of an act passed in that year, "all oyster grounds, lands, and beds included within lands of the State of New Jersey under the tidal waters of the Delaware Bay and Maurice River Cove" are placed under the exclusive control of a State oyster commission, composed of three members, to be appointed by the governor, all of whom should be directly interested or engaged in the oyster business in this region. The commission is authorized to appoint an oyster superintendent, who has immediate supervision of the industry and attends to the enforcement of the law.

The law further authorizes the commission to lease to "applicants therefor any of the lands of the State under the tidal waters of the Delaware Bay and Maurice River Cove south of the line running direct from the mouth of Straight Creek to Cross Ledge light-house, and commonly known as the 'southwest line,'" to be used for the taking, planting, and cultivating of oysters. The granting of leases to nonresidents is forbidden, except in cases where such persons already held ground at the time the law went into effect. Leases are granted for terms not exceeding thirty years, at an annual rental of not less than 25 cents per acre or fraction thereof. Persons having ground or grounds staked up at the time the law went into effect are entitled to have lease or leases for such granted to them in preference to others upon making written application to the commission within a certain time after the act took effect. Leases are to be renewed to the original lessee at the end of each term should he care to continue the business. Penalties are provided for persons robbing such beds. All the natural oyster beds of the bay are exempt from lease.

All vessels and boats engaged in the industry are required to pay a license fee of not exceeding \$2 per ton on the tonnage measurement, and these licenses are to remain in force for one year from the time of issuance. All vessels and boats must be wholly owned by citizens and actual residents of the State.

The law further provides that no oysters shall be taken north of the said "southwest line" except from April 1 to June 15 of each year,

while it is forbidden to take oysters south of the "line" except from September 1 to June 15, both inclusive, of each year. Except on the natural beds south of the "line," no oysters can be taken on ground not leased of the State. The seed beds are located north of the "line," while the market oysters are to be found south of it. One of the best features of the law is the provision requiring that all oysters taken on the natural beds shall be immediately culled, and all shells and other material except oysters at once thrown back upon the beds.

In 1902 this law, with slight variations, was extended to the Keyport region in Monmouth County.

On March 26, 1902, a special act relating solely to Ocean County went into effect. This act is similar in many respects to the Delaware Bay law. One notable exception is in the setting apart of a portion of the grounds to be known and held as public clam-grounds. Leases are to be granted for terms not exceeding ten years, at an annual rental of not less than 50 cents nor more than \$3 per acre or fraction thereof, for the first 10 acres leased, and not less than \$1 per acre for each additional acre or fraction thereof. Persons having ground staked out at the time the law went into effect have first claim on such grounds. Leases are restricted to actual residents of the State. Persons who engage in the business pay a yearly license fee of \$2.50. Oystering on natural beds is restricted to the period between October 1 and April 30, while all oysters are to be immediately culled and the shells and refuse thrown back upon the bed from which taken. In 1902 a similar law went into effect in Atlantic County.

The greater part of the grounds suitable for oyster cultivation are now under the direct supervision of commissions authorized by the legislature, and beneficial results should soon be apparent through the protection given to the planters in their efforts at cultivating oysters. The authoritative surveying and mapping of the leased grounds in the various sections of the State is progressing rapidly and efficiently.

During the year ending October 31, 1901, the New Jersey State Oyster Commission distributed upon the natural beds of the State, exclusive of Delaware Bay, 62,335 bushels of shells. This is done to replenish the natural beds, which are the principal sources of supply of seed oysters for the planted beds. There is no published record of the quantity distributed in the bay.

One of the most serious problems confronting the oyster planter is the securing of enough seed oysters each year to keep the planted beds up to their full capacity. As the natural beds of the State do not furnish oysters enough for this purpose it is necessary for the planters to buy seed from other States. For many years nearly all the seed oysters planted, in addition to those taken from the natural beds, have come from Virginia. It is estimated that the oysters purchased from that State have averaged in late years about \$450,000 in value. On February 16, 1901, a Virginia law forbidding the export of oysters less than 3 inches in length went into effect and prevented the planters from securing their usual seed supply from that source. This very much hampered the planters, and many of them, in 1901, planted only a fraction of the usual quantity of seed. The result of this scarcity of seed does not appear in the present statistics, as the small oysters require several years to attain their full growth. Most of the seed planted now comes from the Raritan River, Staten Island Sound, Newark Bay, and Connecticut. During the season of 1901 seed oysters were unusually plentiful on the natural beds off Keansburg, Monmouth County. During the past two years drum-fish have done considerable damage to the planted beds. In 1902 dynamite was used to destroy them in Tuckerton Bay.

Clams.—During 1901 hard clams were fairly abundant in the waters of this State, but in the summer of 1902 they became very scarce and the price rose unusually high. Owing to the heavy cost of running the large clam vessels of Monmouth County many of the clammers tied up their vessels and went clamming in small boats, which could be run much more cheaply. Except in Monmouth County the softclam business is insignificant; here it is centered largely around Highlands, where a number of wholesale dealers buy from the clammers and ship either in the shell or opened. At Ocean City, in Cape May County, surf clams are gathered along the sea beach, for bait in the line fisheries. None is used for food.

Mussels.—During 1901 mussels were very scarce, there having been no set in most of the counties during the last four or five years. In Monmouth County in 1902 several medium-sized beds were worked. In Burlington and Atlantic counties mussels are used for fertilizer; in Cape May and Monmouth counties they are used principally for food.

Terrapin.—On March 25, 1898, a law was passed by the legislature forbidding the taking of terrapin for three years from the date of the passage of the act, and providing that fishing could be carried on thereafter from November 1 to April 1. The industry was resumed in 1901, and the catch amounted to 8,232 pounds, valued at \$3,135. During 1897, the last year before the law went into effect, 13,528 pounds, valued at \$6,096, were secured. But few persons resumed the business in 1901, which probably accounts for the small quantity taken after three years' complete protection. The fishermen classify the terrapin secured as follows: "Cow," those 6 or more inches long on the under shell; "one-half count," those under 6 inches and not less than 4 inches in length on the under shell; "bulls," all under 4 inches long. Under the present law terrapin under 4 inches in length must be returned to the water. The animal is usually secured by means of a short stick with a hook fastened to the end. With this the fisherman pokes around under the overhanging banks and in likely holes, and hooks the animal out far enough to get hold of it with his hands.

GENERAL STATISTICS.

As compared with 1898 the present canvass shows increases, except in a few instances. In the number of persons employed there was a decrease of 240, but the total investment increased \$392,148. In 1898 the total quantity of fishery products secured in the State was 90,297,118 pounds, valued at \$3,563,766, while in 1901 it was 117,930,964 pounds, worth \$4,755,522, a gain of 27,633,846 pounds and \$1,191,756. The species showing notable increases are the following: Alewives, bluefish, bonito, butter-fish, eels, menhaden, white perch, shad, squeteague, spots, market and seed oysters. The increase in the catch of butterfish is especially noteworthy, having risen from 262,627 pounds, valued at \$8,080, in 1898, to 3,008,301 pounds, valued at \$8,119, in 1901, a gain of 2,745,674 pounds and \$76,039. The principal decreases occurred in croakers, sea bass, sturgeon, king crabs, lobsters, and mussels.

During the last few years cold-storage plants have been erected at various places on the seacoast, in which the surplus catch of the pound nets is frozen when the price is low, to be ultimately shipped when the price advances, or during the winter months when fishing can not be carried on.

The three tables below show, in a condensed form, the number of persons engaged, the number and value of vessels, boats, and of the various kinds of apparatus employed, the value of shore and accessory property, the amount of cash capital, and the quantity and value of the products of the fisheries of New Jersey in 1901:

STATISTICS OF THE FISHERIES BY COUNTIES.

Fishing is carried on in 17 counties of the State. Essex County has no fishing, but there is considerable wholesale trade in fishery products at Newark. Of these counties Bergen, Hudson, Union, Middlesex, and part of Monmouth are on the Hudson River, Staten Island Sound, and New York Bay; Ocean, Atlantic, and portions of Monmouth, Burlington, and Cape May are on the ocean side, while Sussex, Warren, Hunterdon, Mercer, Camden, Gloucester, Salem, Cumberland, and parts of Burlington and Cape May are on the Delaware River and Bay.

Monmouth County leads in the quantity of products, while the large oyster industry of Cumberland places that county ahead so far as total value of catch is concerned. Ocean County also surpasses Cumberland County in quantity, but is far behind both Cumberland and Monmouth in the value of the catch. A feature of the fisheries of Salem County is the immense preponderance of the shad fishery.

The three following tables show the extent of the fisheries by counties.

465

781

1,809

Table showing the number of persons employed in the fisheries of New Jersey in 1901.

THE PRODUCTS BY APPARATUS.

In the vessel fisheries seines lead in the quantity of products secured—over nine-tenths of the catch consisting of menhaden—but dredges, tongs, rakes, etc., rank first in the value of the catch. In the shore fisheries dredges, tongs, rakes, etc., occupy first place, both as regards quantity and value of catch, while the pound net and weir fisheries are second in quantity secured, but are outstripped by gill nets in the value of the yield. A feature of the shore fisheries is the great increase—6,811,064 pounds and \$204,409—shown in the pound-net catch of Monmouth County over 1898. Ocean and Cape May counties also show relatively large increases.

Cod show a great falling off in the pound-net fisheries. In 1897 1,191,000 pounds, valued at \$14,795, and in 1898, 280,000 pounds, valued at \$5,590, were secured, while in 1901 the catch amounted to only 30,686 pounds, worth \$903. According to the reports of the pound-net owners the catch of 1897 was very large, as cod are generally taken in but small quantities in this form of apparatus. Butter-fish, bonito, and squeteague taken in pound nets show large increases over 1897 and 1898, while king crabs have fallen off considerably.

THE MENHADEN INDUSTRY.

While the greater portion of the catch of menhaden is sold to the factories to be turned into oil and fertilizer, large quantities are also utilized by the line fishermen as bait. In 1901 one steamer, two gasoline vessels, and one sailing vessel spent much time during the fishing season in running menhaden from the fishing vessels to Seabright, Monmouth County, for the numerous colony of line fishermen located at that place. These are prepared as "chum" by the fishermen and used for attracting the blue-fish to the vicinity of their boats. At many places the line fishermen have gill nets which they use in catching their own menhaden bait.

In 1901 there were six factories for the preparation of oil and fertilizer in operation, viz: One at Keansburg, two at Belford, and one at Port Monmouth, in Monmouth County; one at Tuckerton, Ocean County, and one at Leesburg, Cumberland County. Part of the plant of the latter factory is at Bakersville, Atlantic County, but as most of the work is done at Leesburg it is all credited there.

Table showing the extent of the menhaden industry in New Jersey in 1901.

FISHERIES OF PENNSYLVANIA.

As Pennsylvania has no frontage on the ocean, its fishery interests are quite limited. With the exception of the small fleet of vessels engaged in line fishing in the ocean during the summer and in working planted oyster beds in Delaware Bay, the fisheries of the State within the scope of this report are confined to the Delaware and Susquehanna rivers. Several of the largest seine fisheries on the New Jersey side of the Delaware River are operated by Pennsylvania, however, while Pennsylvania capital controls a considerable part of the oyster industry of New Jersey and Delaware.

The three tables which follow show in detail the extent of the coast fisheries of Pennsylvania in 1901:

THE FISHERIES BY COUNTIES.

Eight counties in the eastern part of Pennsylvania engage in the fisheries—Bucks, Delaware, Monroe, Northampton, Philadelphia, and Pike counties on the Delaware River, and Lancaster and York counties on the Susquehanna River. Nearly half of the total number of persons employed, over two-thirds of the total investment, and almost one-half of the catch are credited to Philadelphia County. This is largely owing to the wholesale trade of the city of Philadelphia and the vessel fishery for oysters from that city. The relative importance of the fisheries of each county in 1901 is exhibited in the three following tables:

Table showing the number of persons employed in the fisheries of Pennsylvania in 1901.

THE CATCH OF SHAD.

The following supplementary table shows the number of shad caught, and the value, in each county of Pennsylvania on the Delaware and Susquehanna rivers in 1901:

| Counties. " | No. | Value. |
|--|--|---|
| Bucks Delaware Lancaster Nortoe Northampton Philadelphia Pike York Total | $\begin{array}{c} 230, 187\\ 217, 000\\ 78, 679\\ 1, 330\\ 5, 100\\ 145, 831\\ 4, 700\\ 20, 204\\ \hline 703, 031 \end{array}$ | $\begin{array}{r} \$43, 241\\ 29, 264\\ 18, 533\\ 357\\ 1, 275\\ 25, 504\\ 1, 275\\ 4, 879\\ \hline\end{array}$ |

THE FISHERIES BY APPARATUS.

Vessel fishing is carried on in Philadelphia County only, lines and oyster dredges being the apparatus of capture. The line fishery is prosecuted in the summer months, after the oyster season has closed, by a few of the oyster vessels. Pennsylvania has no waters suitable for the cultivation of oysters and is compelled to carry on the industry in other States, principally in Delaware, where Pennsylvanians have bought or leased large tracts of suitable ground.

Some of the oldest seine fisheries in the United States are to be found on the Delaware River. A few of the fishing shores at present in use were cleared and operated by the Indians long before the white man settled in the country. The seine fisheries are operated primarily for shad and alewives, though various other species are obtained in smaller quantities. Gill nets are also used extensively, and in 1901 the catch, consisting principally of shad, was greater in value than that taken in seines.

The following tables show the quantity and value of products in the vessel and shore fisheries by each form of apparatus:

| Species | and apparatus. | | Philade Count | |

THE WHOLESALE FISHERY TRADE OF PHILADELPHIA AND CHESTER.

There is a large wholesale trade in fresh, salted, and smoked fish, oysters, sponges, and other fishery products in Philadelphia, while a much smaller business is carried on in Chester. The following table shows the persons employed, wages paid, and capital invested in both cities:

Persons and capital in the wholesale fishery trade of Philadelphia and Chester in 1901.

FISHERIES OF DELAWARE.

Compared with 1897 the fisheries of Delaware in 1901 show a decrease in the number of persons employed and in the value of the product, the number of persons decreasing from 2,392 in 1897 to 1,998 in 1901, and the value of the product from \$252,123 to \$203,372 in the same period. The returns for 1897 differed little from those of 1892 and the three years immediately preceding.

More than half of the decrease occurred in the sturgeon fishery, the output of which in 1897 was valued at \$34,750, and in 1901 at \$10,444. This decrease occurred notwithstanding the fact that caviar and dressed sturgeon were much higher in price in the latter year, the caviar increasing from 37 to 65 cents per pound, and the dressed sturgeon from less than $5\frac{1}{2}$ cents in 1897 to $8\frac{1}{2}$ cents per pound in 1901. In 1901 this fishery gave employment to 122 men, using 57 boats, worth \$5,690, and 37,680 vards of drift gill nets, worth \$5,190; the catch was 553 sturgeon, weighing 86,199 pounds, which vielded 10,307 pounds of caviar, worth \$6,766, and 44,499 pounds of dressed sturgeon. worth \$3.678. The sturgeon product of the State is now less than 7 per cent in quantity and 35 per cent in value of what it was ten years ago, notwithstanding an increase in the number of boats employed. At Delaware City, one of the principal centers of this fishery, there were 422 kegs of caviar produced in 1895, 244 in 1896, 106 in 1897, 54 in 1898, 35 in 1899, 20 in 1900, and only 6 in 1901.

The yield of shad also shows a large decrease in number, but from the point of view of the fisherman this is more than offset by an increase in the value, the fish averaging \$11.09 per hundred in 1897 and \$15.61 in 1901. More than 90 per cent of the shad in this State are taken by means of drift nets, which are operated principally in Delaware River, especially at Newcastle, Delaware City, and Port Penn, and to a small extent in the headwaters of Nanticoke River. In 1891 this fishery employed 397 men, using 201 boats worth \$8,826, and 236 nets worth \$16,833, and the catch of shad numbered 394,952. In 1901 the fishermen numbered 443, using 244 boats worth \$13,726, and 285 nets worth \$13,842, and the catch amounted to 329,750 in number. This represented an average for each man of 995 shad in 1891 and only 744 in 1901.

The oyster business, the most important fishery industry of the State, has changed little during the last ton years. As in other Middle Atlantic States, there is a steady decrease in the resources of the public reefs of Delaware, with a corresponding increase in private oyster culture. At the present time most of the market oysters obtained from the public reefs are scarcely more than large enough for planting purposes; but owing to local conditions and regulations they are sold in the markets of the adjacent towns.

The returns presented in the subjoined tables show only imperfectly the extent of the oyster resources of this State. Most of the oysters credited to Pennsylvania and a small percentage of those credited to New Jersey were taken from within the limits of the State of Delaware; but they have been credited to Pennsylvania and New Jersey, respectively, owing to the fact that they were taken by vessels owned in those States. During the year covered by the returns 15 nonresident vessels engaged in dredging oysters on the natural reefs, and 34 in cultivating oysters on the private areas in this State, whereas only 21 resident vessels engaged in this industry. The oyster fishery is centered at Bowers Beach and Little Creek in Kent County, but many oysters are tonged near the mouths of creeks in that county and also in Sussex County. At Seaford, Sussex County, about 125 persons are employed in the wholesale oyster trade, receiving supplies from Chesapeake Bay in Maryland.

The yield of alewives, perch, squeteague, and striped bass shows a decrease of about 50 per cent compared with 1897, while that of German carp, cat-fish, and eels shows an increase. These species are taken mostly by seines, gill nets, and fyke nets, and many eels are taken in pots. The fisheries are not centered in particular localities, but are well distributed throughout the State, except the squeteague, which is taken mostly below the mouth of Delaware River. The increase in the yield of German carp is especially noteworthy. Ten years ago very few were caught, but in 1897 111,300 pounds were reported, and in 1901 the catch amounted to 198,040 pounds.

While the lobster fishery of Delaware is of little economic importance, it is interesting on account of its representing the southernmost limit of that fishery on the Atlantic coast. It is prosecuted at Lewes, in Sussex County, and the lobsters are taken in pots set in the vicinity of Delaware breakwater. In common with that on other parts of the coast, the yield of lobsters in Delaware shows a gradual decrease. In 1891 the eatch was 8,200 pounds, in 1897 it was 5,095 pounds, and in 1901 it was further reduced to 2,760 pounds.

The factory at Lewes, Del., receives large quantities of menhaden for conversion into oil and fertilizer. These fish, however, are credited as part of the product of the fisheries of New York, owing to the fact that the vessels taking them are owned in that State. In 1901 46,260 tons of menhaden were converted into \$325,982 worth of oil and fertilizer. With the exception of Virginia this was a greater quantity of menhaden than was utilized in any other State, and represented onesixth of the total product of menhaden in the United States.

The extent of the fisheries of Delaware in 1901 is shown in the following tables.

FISHERIES OF MARYLAND.

In 1901 the fishery products of Maryland show a small increase in value over 1897, at which time the State ranked first among the Middle Atlantic States in the value of its fisheries. Notwithstanding this increase, the State is now surpassed in the value of fishery products by New Jersey, Virginia, and New York. The value of Maryland's fishery resources depends largely upon the oyster, the yield being worth more than four times as much as that of all other products combined. The greater part of the capital in this fishery is invested at Baltimore in oyster canneries, shucking houses, and dredging and transporting vessels.

Though the oyster season of 1900–1901, compared with 1897–98, shows a decided decrease in the number of bushels taken, there has been an increase in the value of the catch. The best catches by dredging vessels were from grounds in the upper part of Chesapeake Bay, and being near Baltimore were sold direct to dealers there instead of to transporting vessels.

The diminished supply of oysters on natural beds in some localities has induced many ovstermen to engage in planting on private beds. The benefits of ovster-planting are already apparent, and the future promises greater success, provided more ample protective laws are enacted. It is difficult, however, to pass laws that would suit both ovstermen and crabbers in Dorchester and Somerset counties, as the crabbers object to crabbing grounds being taken for oyster-planting purposes. Maryland oyster planters have also suffered considerably through a law passed by the State of Virginia prohibiting the shipment of seed ovsters from that State, thus cutting off a prolific source of supply. Before this law went into effect Maryland planters could obtain their seed ovsters from Virginia at an average cost of 15 cents a bushel, while now the prices range from 20 to 40 cents. The principal sources of supply of seed ovsters are the Potomac, Little Choptank, Choptank, and Honga rivers, and Eastern Bay. The most important planting grounds are in Fishing Bay, Pocomoke Sound, Chincoteague Bay, and the Nanticoke and Wicomico rivers. The planters in these waters are assured of a considerable degree of safety, as the crabbing industry is practically of no importance there.

The following extract from an editorial in the *Baltimore Sun* of April 20, 1903, may be of interest as showing the attitude of those who advocate more extensive oyster planting:

Oyster planting.—A dispatch to The Sun from Prince Frederick says that many tongers in Calvert County have taken up lots for planting oysters. This is gratifying intelligence and indicates that the oystermen are beginning to awaken to the situation. There has been much complaint lately of seed oysters being taken from the State. It is to be hoped that a great number of lots will be staked off before the

supply of seed ovsters is exhausted. Then the ovster planters will have to go to the legislature for the enactment of a law which will protect them from marauders who come by night and carry off their property, as well as those who despoil them by legal process. The present law under which these lots are staked off and planted affords no manner of protection to the industrious planter. Planting on natural beds is prohibited, and the common practice is for persons interested to wait until the ovsters in a private lot are marketable, and then they go into court and prove that at some time long past the lot staked off was a natural bed. This is easy to do, as in past years nearly the whole bottom of the coves and creeks where oysters will grow had oysters on them. After this proof is submitted the court orders the lot to be vacated, and then outsiders carry off the ovsters which have been planted. This has gone on so regularly and persistently that it is surprising to hear that men will take the risks. If all or a large majority of those interested in the ovster industry in a locality become planters, then all will be equally interested in protecting the beds. Then the ovstermen will, perhaps, cease their opposition to the enactment of a law which will protect planters in their rights. * * *

While Maryland is neglecting her opportunities and frittering away a vast mine of wealth, other States, by enlightened legislation, are growing rich from oyster bottoms greatly inferior to ours. Not only is a great food supply disappearing, but people are losing a profitable employment and oyster canneries are moving from the State to other States where a supply of oysters can be procured.

As a rule, oysters are marketed as soon as caught, but at Solomons, Calvert County, and vicinity the oystermen bed their catch and let it remain down for a better market. This insures an increased price, the oysters having a chance to fatten. This is especially advantageous during the early part of the season, when the oysters are rather poor and the demand for them light.

With the exception of Baltimore the most important oyster centers in the State are Cambridge and Crisfield, the number of men and boats engaged in the fishery from these towns being very much greater than from Baltimore. Deal Island, Oxford, Tilghman Island, and St. Michael also have large investments in this fishery.

Clams.—Clams are of commercial importance in only two counties, Somerset and Worcester. In the former they are taken in Pocomoke Sound by fishermen from Crisfield and vicinity. In 1901, however, a few men from Fairmount fished for clams to a limited extent in Tangier Sound. In Worcester County the entire catch is taken from Chincoteague and Sinepuxent bays.

Crads.—The erab fishery is next in commercial importance to the oyster, though the investment in boats, apparatus, and shore property is small compared with that in the oyster fishery, and practically no revenue is derived from it by the State, as no license of any kind is required, except in Dorchester County, where a fee of \$2.50 is charged for the privilege of scraping. No restrictions as to seasons or size of crabs are imposed. There has been a noticeable increase in this fishery since 1897, and the outlook for the industry appears bright, though the catch in most localities in 1902 was small. The demand for both live crabs and crab meat is constantly growing, and the number of factories engaged in the preparation of crab meat is

increasing. It is not unlikely that in the near future there will be a demand for crabs during the winter as well as in the summer.

Practically the entire catch of soft crabs is taken in scrapes and scoop nets, though a few are caught in small seines of from 40 to 50 yards in length, which are handled by two men. The seines are used interchangeably with scoop nets, the latter being used on low tides and the former on high tides or when the water is too thick to see the crabs.

With the exception of a few hard crabs taken in scrapes with soft crabs and in dredges during the oyster season, the catch is taken on trot lines. These lines vary in length from 200 to 1,000 yards, and are baited principally with beef tripe and cels. As the transportation companies object to handling tripe, it is being superseded by cels.

Though the crab industry is of greatest importance on the eastern shore of the State, quite a number are caught on the western shore, and in 1902 increased catches were taken in Anne Arundel County and in the vicinity of Solomons Island, Calvert County. The preceding cold winter seemingly did not affect the supply in these counties, and with the decreased catch on the eastern shore and advanced prices many residents of the western shore were encouraged to engage in the fishery.

Shad.—This is the most important species of fish taken in the waters of the State and, together with alewives, is the incentive for a great many men to engage in fishing. This is especially applicable to the gill-net fishermen, who set their nets as soon as the run of shad begins in the spring and fish until the close of the season, when the nets are laid aside and other occupations are followed until the next spring. Although the investment is small, the shad fishery sometimes proves quite remunerative to a large number of men. With the exception of Betterton and vicinity, where the catch of shad in gill nets was exceptionally heavy, this species shows a falling off of nearly 50 per cent in 1901 compared with 1897. It is probable, however, that the decline is only temporary, and is attributed by many fishermen to the late and cold spring, the low temperature of the water in the rivers tending to prevent the shad entering for the purpose of spawning. While the catch was small, the fishermen were compensated to a large degree by advanced prices. Shad are taken principally in gill nets, pound nets, seines, and bow nets, five-sixths of the total yield of the State being from the gill-net and pound-net fisheries.

Alewives.—Alewives are next in importance to shad and are taken during the same season. Practically the entire catch is secured in pound nets and seines, though in some localities many are also caught in gill nets. Like the shad, and for similar reasons, they show a decrease in 1901 as compared with 1897.

Menhaden.—The increase in this species over 1897 is due to the fact that during that year the factory at Crisfield purchased its supply

from Virginia vessels, while in 1901 it employed its own steamer and bought only a small proportion from vessels outside of the State.

Striped bass and white perch.—Striped bass is one of the best selling species taken in the State. Very little change has taken place in its abundance, though it was a more special object of capture in 1901 than in 1897, an increased number of purse-seiners fishing for this species and incidentally for white perch. There has been a noticeable decline in the catch of white perch since 1897.

German carp.—While this species is not of great importance compared with many others, there has been a large increase in the catch, especially in Harford, Kent, Calvert, Cecil, Charles, and Prince George counties. One small pound net set in the Patuxent River, off Calvert County, caught 10,000 pounds of carp during the fall of 1901, which were sold at an average price of 4 cents a pound.

Gar pike.—This species is not of great importance in any one locality, but in the aggregate quite a number are caught in pound nets and shad gill nets. They are sold principally to colored people for a few cents a piece and it is not uncommon at some places to see several colored people awaiting the return of fishermen to buy their gar pike.

Terrapin.—This fishery has decreased in value within the past ten years from \$22,333 in 1891 to \$1,139 in 1901, and it is now followed in but few localities as a business, most of the catch being taken incidentally by men engaged in other pursuits. If this decline continues it will be only a few years when the terrapin will be practically extinct in the State.

Other species.—Other important species are squeteague, cat-fish, butter-fish, sturgeon, and cels, all except squeteague and butter-fish showing a decrease since 1897. The increase in these two species is chiefly due to the extension of the pound-net fisheries in the Atlantic Ocean off Worcester County.

Apparatus.—Taking the value of the catch as a basis, the most important kinds of apparatus of capture are tongs and nippers, dredges, pound nets (including trap nets and weirs), scines, crab scrapes, lines, gill nets, scoop nets, and fyke nets, in the order named. The catch by these kinds of apparatus ranged from \$1,873,905 worth taken by tongs and nippers to \$24,211 worth in fyke nets. Minor forms of apparatus were used, but their catches were small.

With the exception of \$14,384 worth of clams and \$99 worth of terrapin, the catch by tongs and nippers consisted of oysters. Two kinds of tongs are used, the ordinary shaft tongs and the patent tongs, the former being in much more general use. The employment of patent tongs is confined almost exclusively to Kent, Calvert, and St. Mary counties, their use being general in the two latter counties near the mouth of the Patuxent River, where they are especially advantageous owing to the depth of water being too great in most places for shaft tongs. The shafts of the latter vary in length in different parts of the State from 16 to 35 feet, an average being about 18 feet. The use of winding gear for operating patent tongs makes necessary the employment of larger boats than for shaft tonging, these larger boats being generally used later in the season for dredging.

Pound nets are fished principally in the spring for shad and alewives, but very often they are set in rivers in the fall for striped bass.

Two kinds of seines are used, haul and purse seines. The former are used principally for alewives, striped bass, shad, white perch, and other fishes, while menhaden, striped bass, and white perch are the most important species taken by the latter. Haul seines are usually fished in the spring, but often in the fall also. Purse seining for striped bass and white perch is carried on during the summer. Haul seines are in most cases fished in the rivers, an average crew consisting of from four to six men, except on the Potomac and Susquehanna rivers, where longer seines are used. The longest seine used on the Maryland side of the Potomac River in 1901 was 1,600 yards, 22 men being necessary to handle it and look after the catch. The longest seine used in the State was on the Susquehanna River in Cecil County. Its length was 2,200 yards, and there were 65 men in the crew. Purse seines are fished in the open waters of Chesapeake Bay for menhaden, striped bass, and white perch. Almost the entire menhaden catch of the State was taken by the steamer already mentioned as being owned at Crisfield. Purse seining for striped bass and white perch is confined exclusively to fishermen from Kent County, Rock Hall being the center of the fishery. Vessels of about 5 net tons and over are used. The crew usually consists of seven men, and a trip varies in length from one to two weeks, according to the abundance of fish. This fishery, while not new, has been prosecuted more vigorously during recent years than formerly and has proved quite profitable, notwithstanding the large outlay and heavy running expenses. The crew, as a rule, work on shares.

Two kinds of lines are used, the trot line for hard crabs and catfish, and the hand line for sea bass, squeteague, and various other species. The same kind of line is used for crabs as for cat-fish, except that no hocks are needed for the former. Crabs constitute over 90 per cent of the entire line catch.

The preponderance of shad over other species taken in gill nets is so great that this apparatus may be said to be used primarily for that species. In Kent County, however, large catches of striped bass and white perch are made in sunken gill nets set during the winter and early spring before the run of shad has begun. As soon as that species appears the anchors (usually bags of sand) are removed from the nets and the latter allowed to drift. The drift gill net is the most important style of gill net used, though quite a number of shad are also taken in stake gill nets. Drift gill nets vary in length from 50 yards set in the rivers to 2,200 yards set in Chesapeake Bay. The longest

are used in the bay off Betterton, Kent County. An average of those used at this place is about 1,400 yards. Nets of this length consist of sections of from 200 to 300 vards each, fastened together while fishing. As the nets are set about 3 feet under water it is very seldom necessary to make any provision for the passage of vessels, as most of the latter can go over the nets without injuring them. Occasionally, however, in the case of larger vessels or steamers, it is necessary to separate the net to allow them to pass. Another advantage in setting the nets under water is to prevent them catching logs or driftwood. In fishing one man can handle a net from 50 to 100 yards long, while it takes two men for a net varying in length up to 1,000 yards, or two of the shorter ones. Three men are commonly engaged in handling the longest nets used in the bay. In some localities drift gill nets are fished exclusively in the davtime, while in others they are fished during the day in the early part of the season when the water is muddy, and, later, when the water becomes clear, they are fished at night, the men usually going out about midnight and remaining until noon the next day. The nets are then spread out and dried before using them again.

A comparatively new and profitable style of net, called "buck net," is used in a few localities. These are from 225 to 400 yards in length, from 25 to 40 feet deep, and are fished in the open waters of Chesapeake Bay, the catch consisting principally of blue-fish and occasionally a few Spanish mackerel. The net is hauled around a school of fish, the latter gilling in it. A crew of about five men is required in handling a net of this kind.

Owing to the almost complete disappearance of sturgeon in the rivers of the State, very few sturgeon gill nets are used; but in Worcester County an increase in the catch of this species is shown, due to an extension of the fishery by fishermen from New Jersey.

Men.—The total number of persons engaged in the fisheries of Maryland in 1901 was 36,260. Of this number, 16,880 are credited to the shore fishery; 12,553 were engaged in oyster shucking and packing houses, crab houses, and other occupations incidental to the fisheries; 5,715 were engaged on fishing vessels, and 1,112 on transporting vessels. One hundred and ten men were engaged both in the shore and vessel fisheries. There has been a decrease of 6,552 since 1897 in the total number of persons engaged in the State, this being due principally to the decline in the oyster fishery:

Investment.—The total investment in the fisheries was \$6,506,066. Of this, \$2,297,515 represents the cash capital employed; \$2,164,749, the amount invested in shore and accessory property; \$1,137,362, the value of 955 fishing and 382 transporting vessels with their outfits; \$553,526, the value of 11,498 boats under 5 tons. The remainder represents the value of the apparatus used.

In the following tables is shown, first, the number of persons engaged in the fisheries; second, the vessels, boats, and apparatus used and the value of the shore and accessory property and cash capital employed; third, the quantity and value of fishery products taken in the State during 1901, the statistics on oysters, however, being for the season of 1900–1901.

THE FISHERIES BY COUNTIES.

While the fisheries are prosecuted on both the eastern and western shores of the State, by far the larger catches are made in the former section, this being particularly true in the case of oysters and crabs. Somerset and Dorchester counties possess the most valuable fishery resources in the State, this preeminence being due to oysters and crabs. Dorchester leads slightly in the catch of ovsters, but Somerset's valuable crab fishery more than offsets this advantage, three-fourths of the State's soft-crab catch being taken in this county. Practically all of these are handled at Crisfield and Deal Island and shipped from these points to the large cities throughout the United States and Canada. Talbot County leads in the catch of hard crabs, the principal part of the catch being used in factories, where the meat is extracted and shipped in tin buckets. Most of these factories are located at Oxford, St. Michaels, and vicinity, and Tilghmans Island. Large quantities of hard crabs are also taken at Cambridge, Dorchester County, and Mount Vernon, Somerset County, practically all of these being shipped alive. The fisheries proper are prosecuted to the greatest extent in Worcester County. This is the only county bordering on the Atlantic Ocean, and most of the fishing is now done by means of pound nets, which, since 1897, have increased from 1 to 7 in number. Talbot ranks next to Worcester County in its pound net fishery, the principal catches being made in the Choptank River and in Chesapeake Bay off Tilghman Island. Squeteague is the most important species taken in Worcester, and shad and alewives in Talbot County.

Increased values are shown in 1901 compared with 1897 in the fisheries of Anne Arundel, Calvert, Charles, Kent, Queen Anne, Somerset, and Wicomico counties, while decreases are shown for the other fishery counties, especially in Caroline County, where a decline from \$22,012 in 1897 to \$5,787 in 1901 has taken place. This is due almost entirely to the decrease in shad. With the exception of Charles County, the counties showing increased values owe it to the better prices received for oysters. A decided improvement is shown in the crab fishery in every county except Kent and Queen Anne. This compensated to a degree for the poor showing made in some of the other fisheries, particularly the shad and alewife. Harford and Worcester counties are the only counties showing an increase in shad. The former county represents a natural increase, while in Worcester County it was due to more extensive fishing. On the basis of persons employed, the most important counties are Baltimore (including Baltimore city), Somerset, and Dorchester, where 9,642, 6,340, and 5,229 persons, respectively, were engaged. Baltimore's lead over the other counties is due entirely to its wholesale oyster trade. The extensive haul-seine fisheries formerly prosecuted in Cecil County are being superseded by pound nets, the advantages of the latter being reduction of first cost and economy of operation. Baltimore and Kent counties have the most important fyke-net fisheries.

The three following tables show the extent of the fisheries in each county of Maryland in 1897:

| Counties. | On vessels fishing. | On vessels transport- ing. | In shore or boat fisheries. | Shores- men. | Total. |
|--|------------------------|--|--|-------------------------------|---|

Of the rivers shown in the preceding table, the Potomac, Susquehanna, Nanticoke, and Pocomoke have shad fisheries in two States, including Maryland. The value of Virginia's shad catch in the Potomac is over seven times that of Maryland. The catch from the Susquehanna River in Pennsylvania is nearly three times as valuable as in Maryland. Delaware's catch from the Nanticoke slightly exceeds that of Maryland. The proportion of Virginia's catch in the Pocomoke was comparatively small. The total yield of shad for each of the above rivers is shown, by States, in the following table:

| Waters and States. | No. | Lbs. | Value. | Waters and States. | No. | Lbs. | Value. |
|--|----------------------|----------------------|----------------------|--|--------------------|---------------------------|--------------------|

a Exclusive of duplication.

a Exclusive of duplication. b These lines are used primarily for hard crabs, the soft or shedding crabs being taken with the hard crabs as "doublers." e Includes 95,000 hard crabs, valued at \$235, taken in crab scrapes, and 67,000 hard crabs, valued at \$500, taken while dredging for oysters.

THE WHOLESALE FISHERY TRADE.

In the quantity of oysters handled Baltimore ranks first not only in the State, but in the entire country. This is largely due to its accessibility from the oyster grounds and its transportation facilities. So important is the shucking and packing trade of Baltimore that during the oyster season the leading railroads send out daily trains, several cars in length, loaded entirely with shucked ovsters, which are widely distributed throughout the Western States. Many dealers, however, are finding it cheaper to have their oysters shucked in small towns contiguous to the oyster-grounds and shipped to Baltimore by This is also the case with firms engaged in the crab-meat steamer. While Baltimore handles the larger portion of the State's industry. ovster catch, owing to direct connection of towns on the eastern shore

515

of the State with New York and Philadelphia, these two cities receive large shipments of fish, the demand being greater and the prices higher in many cases than in Baltimore.

The burning of ovster shells for lime is an industry of some importance in Baltimore, the product being used largely as a fertilizer. The use of crushed and ground shells as a food for fowls is also growing. Owing to the lessening quantity and higher prices of oysters the canning industry of this city is decreasing in value, several large firms having moved to other States. Next to Baltimore the largest quantities of ovsters are handled at Cambridge, Crisfield, and Oxford, many shucking houses being located at these places. Crisfield still continues to be the most important crab-shipping point in the United States and, together with Deal Island, handles practically the entire soft-crab catch of the State. On account of the small capital necessary, the number of crab firms at Crisfield is increasing yearly and is no doubt responsible for the low prices received by the fishermen, as these firms, in their endeavors to get contracts with commission houses in the larger cities, are compelled to underbid competitors in fixing prices for the following season.

Hard crabs are handled principally at Oxford, St. Michaels and vicinity, Tilghman Island, and Cambridge. With the exception of the latter, these places handle the crab meat almost entirely.

The following table shows by localities the number and value of establishments, cash capital employed, and number of persons engaged in the wholesale fishery trade of Maryland in 1901:

| | Estab | lishments. | Cash | Number |

Table showing the wholesale fishery trade of Maryland in 1901.

FISHERIES OF VIRGINIA.

The fisheries of Virginia, as compared with those of the other Middle Atlantic States, ranked first in the quantity of products in 1901.

The last two canvasses (1897 and 1901) of the fisheries of this State by the United States Fish Commission present some interesting comparisons. The total capital invested in shore property, vessels, fishing apparatus, and cash capital in 1897 amounted to \$2,891,536, and in 1901 to \$3,633,104, an increase of \$741,568. The number of fishermen and shore employees in 1897 was 28,277, and in 1901, 29,325, an increase of 1,048. Of the employees in 1901, 5,565 were on vessels, 18,492 on small boats in shore fisheries, and 5,268 in wholesale fish markets, menhaden factories, and oyster canneries.

The products in 1901 as compared with 1897 show an increase of 861,599 bushels in the quantity and of \$881,773 in the value of the oyster catch. In the other fishery products there has been an increase of 94,158,216 pounds and of \$552,113. The total yield and value of the oyster fishery in 1897 was 7,023,848 bushels, of \$2,041,683 value; in 1901, 7,885,447 bushels, of \$2,923,456 value. The fishery products, exclusive of oysters, in 1897 amounted to 228,827,013 pounds, of \$1,137,815 value; in 1901, to 322,985,229 pounds, of \$1,689,928 value.

The greater part of the fish are caught by pound nets, gill nets, and haul seines, in each of which, since 1897, there has been a material increase in number. Pound nets have increased from 1,250 to 1,590, gill nets from 9,307 to 10,437, and haul seines from 107 to 257.

Alewives, one of the most abundant food species, have increased in both the quantity and value of the catch, which was 13,689,510 pounds in 1897, valued at \$70,841, and 13,913,444 pounds in 1901, valued at \$115,424. There was an increase of 905,690 pounds in the squeteague taken and of \$38,026 in the value.

The shad catch is an important feature of the fisheries of Virginia, the most of it being taken in pound nets, of which many are owned and worked by planters who farm near the fishing-grounds. The farmer fishermen take up their pound nets at the close of the shad season. The shad catch of 1901 shows a large decrease from that of 1897, which is accounted for by the unusually cold and backward spring. The season at its best is short, and in 1901 the fish were late in arriving, after which much time was lost from the weather being unfavorable for fishing. The shad catch in 1897 amounted to 11,529,474 pounds, valued at \$304,448, and in 1901 to 6,972,212 pounds, valued at \$366,203, a decrease of 4,557,262 pounds in quantity and an increase of \$38,245 in value, the better price received by the fishermen in 1901 more than compensating for the reduced catch. The shad in 1901 were extra large and of fine quality, and found a ready market at the seaside resorts, as well as in the northern markets, the demand being steady and prices satisfactory. Crabs continue plentiful, with an increasing demand for those shipped alive, for cooked meat picked from the shell and shipped in bulk, and for that hermetically sealed in tin cans, the latter being distributed as far as the Pacific coast. The crab catch in 1897 amounted to 6,399,514 pounds, valued at \$68,245, and in 1901 to 7,401,701 pounds, of \$118,835 value, an increase of 1,002,187 pounds and of \$50,590.

Oysters comprise more than three-fifths of the value of the fisheries of Virginia. The oyster season from September 1900 to May 1901 was the most successful for many years. The yield of the oyster fishery of Virginia in 1891 was 6,074,025 bushels, of \$2,524,348 value; in 1897, 7,023,848 bushels, of \$2,041,683 value; and in 1901, 7,885,447 bushels, of \$2,923,357 value. The product of market oysters in 1901 was 2,991,144 bushels from natural rock or native beds and 3,076,525 bushels from private beds, and of seed oysters 1,817,778 bushels were taken from their native beds and replanted on private beds.

Yearly the area of native oyster grounds decreases, as a result of overworking the beds and the abandonment of those that have become unproductive. As soon as a bed is depleted of oysters it is available for rent by any citizen at \$1 per acre per year. This has proved of much benefit to the State, both on account of the revenue derived and in the reestablishment of beds upon a commercial basis. Grounds once noted for an abundance of fine oysters were, from overworking, cleaned of oysters and abandoned, after which they were leased from the State by private parties who prepared and reseeded the grounds, watched and cared for them until they equaled or exceeded their former abundance. Others leased land up the rivers on bottoms that had never been known to have an oyster on them; seed oysters were planted on these grounds, and new areas of good oyster beds resulted.

In some cases leased lands have been used only for a short bedding of market oysters that had been taken from their native beds. This gave the owner protection during the few months the oysters remained on the private beds and fattened. In case of an overstocked market with much reduced prices, many cargoes are returned and planted on private beds. These oysters having been counted as from natural beds were not again counted from private beds, which accounts in some cases for the entire absence or very small quantity of oysters from private beds in counties that are known to have leased oyster lands.

ENDLESS-CHAIN SCRAPER USED IN OYSTER-SHUCKING ESTABLISHMENTS.

Oysters are brought in vessels from the oyster beds to the plants of the wholesale dealers and there unloaded into storerooms adjoining the shucking rooms on the wharf. From the latter they are carried to the shucking benches. Shucking benches extend the entire length of the long, low building, some 100 to 200 feet long, there often being several of the tables with an aisle between. Each of these long tables has partitions dividing it into stalls just large enough for the oyster

opener to work to advantage. The opener picks up an oyster from the pile before him, placing its edge on an upright pin, and with a small hammer breaks off the tip end, then inserting his ovster knife with a quick motion, flips off the top shell which drops down a spout by his side; another quick motion with the knife and the ovster is thrown from the shell into a measure, the shell following the first one down the spout. From the chute the shells fall into an oval-shaped trough that extends under the entire length of the long table. An endless chain passes over the trough to which, every 2 or 3 feet, is attached an iron scraper that scrapes the shells as they fall from the hands of the opener. Arriving at the end of the table, the shells fall into another trough running at right angles, which is also provided with an endless chain with scrapers that passes on outside of the building and up an incline of 50 feet in height, out on an extended arm some 50 feet, around which it returns and continues its endless course. The extended arm at the top is provided with openings through which a continuous stream of shells falls so long as the 150 openers are at work. When one pile of shells reaches up to the 50foot level the first opening is closed, the shells falling through the next opening, starting another pile from the ground. The endless chain is 1,000 feet long and is driven by a 45-horsepower steam engine. This appliance was first used in the oyster industry during the season of 1899 and 1900, removing 125,000 bushels of shells.

In the season of 1900–1901, 190,000 bushels of shells represented the bulk of the season's work of opened oysters by one firm. At the close of the season these shells were all removed and scattered over the private oyster beds of the firm, for the spat or young oysters to catch on soon after hatching out.

For many years the removal of the large amount of shells was quite a tax on the business. Shells were gladly given away to anyone who would remove them. Then as they came more in demand for road building, the filling of low lands, for making lime, and other purposes, a small price of 1 cent or less a bushel was paid. As the leasing of land for oyster culture increased, the shells came largely in demand for planting on oyster beds and were so used for several years, the price advancing to 2 cents a bushel. During the years of depression their use was discontinued. With the return of more prosperous years and a large increase of private beds, an active demand for shells to plant called for nearly all the supply, at prices ranging from 3 to 4 cents a bushel, adding many thousands of dollars to the receipts of the dealers.

FISHING WATERS AND SEASONS.

The State of Virginia is bountifully supplied with waters that produce many species of food fish. Beginning on the south near the State line of North Carolina, pound nets and haul seines are used all along the beach to Cape Henry and in the Chesapeake Bay and Potomac River, as well as on the eastern shore of Virginia in Accomac and Northampton counties. Pound nets are set in the early spring as soon as the weather will permit, but most of them are taken up when the run of shad is passed. A few are again fished for a short time in the fall, and others are fished all the season from March to November, the length of seasons depending on weather conditions. Much time and property are often lost from unfavorable weather. Haul seines are used during the same time mentioned for pound nets. These are worked by hand, horses, and in a few cases by steam.

The several navigable streams, including the Nansemond, James, York, Rappahannock, and Potomac rivers, with their numerous branches, creeks, and bays, are nearly all fished, more or less, for shad, and but very little except during the shad season. For a long time the rivers have no doubt been overfished, being lined with stake gill nets, haul seines, and a few other appliances of capture. So few of the local species remain that it does not pay the fishermen to follow the business after the run of shad is over. Citizens living along the upper tide waters now report very few, if any, shad seen in these waters, which formerly were so plentifully supplied with them. The same conditions obtain as to alewives and all other migratory fish.

It has been noted that the fishery products of Virginia for 1901 show quite an increase over those of 1897. This may be partly accounted for by an increased quantity of fishing apparatus in the waters of Chesapeake Bay and the near shore waters of the Atlantic Ocean. The number of pound nets increases every year, and they are placed farther from shore in deeper water.

While the river fisheries have to a large extent become exhausted, or at least unprofitable, their place has been filled by the planting of oysters on private beds. A large portion of the beds of the rivers before mentioned are now leased from the State and planted with oysters as far up as the waters are at all suitable. Much of this oyster ground was never known to have had an oyster on it, while other sections were abandoned oyster beds. Nearly all of these private oyster beds have proved financially successful, except when excessive rains have freshened the water and covered the oyster beds with silt, killing thousands of bushels of oysters. The two eastern counties of Virginia—Northampton and Accomac—have almost continuous shore lines of fishing-grounds in the waters of Chesapeake Bay and the Atlantic Ocean. The representative catches of this district embrace menhaden, blue-fish, alewives, crabs, and oysters, with smaller quantities of several other species.

The three tables which follow show the number of persons employed, the number and value of vessels, boats, and apparatus of capture, the value of shore and accessory property, the amount of cash capital, and the quantity and value of products in the fisheries of Virginia in 1901. Persons employed.

STATISTICS BY COUNTIES.

In 1897 the fisheries of Virginia were carried on in 34 counties, but since that time they have ceased to be of commercial importance in Dinwiddie and Hanover counties. The following tables give detailed statistics of the fisheries of each county for the year 1901:

Table showing the number of persons employed in the fisheries of Virginia in 1901.

| Counties. | In vessel fisheries. | On vessels transport- ing. | In shore or boat fisheries. | Shoresmen. | Total. |

a 6,972,212 pounds.

THE PRODUCTS BY APPARATUS.

The products of the vessel fisheries of this State amounted to 277,812,456 pounds, valued at \$1,080,475, and those of the shore fisheries to 100,370,902 pounds, valued at \$3,532,909. The yield of the vessel fisheries consisted of menhaden with purse seines, 262,877,262

pounds, \$417,765; oysters with dredges and tongs, 14,749,490 pounds, or 2,107,070 bushels, \$644,169; and hard clams with tongs, etc., 185,704 pounds, or 23,213 bushels, \$18,541. In the shore fisheries a greater variety of apparatus was employed and the products comprised upward of thirty different species. Seines secured 9,987,821 pounds, \$122,774; gill nets, 3,204,111 pounds, \$133,171; pound nets, 34,620,083 pounds, \$673,789; slat traps and weirs, 84,780 pounds, \$2,559; fyke nets, 668,837 pounds, \$28,453; lines, 8,415,124 pounds, \$105,894; eel pots and spears, 47,700 pounds, \$2,132; minor apparatus, 320,103 pounds, \$25,976; dredges and tongs, 40,488,639 pounds, or 5,778,377 bushels of oysters, \$2,279,287; clam tongs, hoes, and rakes, 1,578,976 pounds, or 197,372 bushels of clams, \$116,236; and crab scrapes, 994,728 pounds, or 2,996,184 soft crabs in number, \$42,638.

The following tables show, by counties and species, the quantity and value of products taken with each form of apparatus in the vessel and shore fisheries of Virginia in 1901:

MENHADEN FISHERY.

The menhaden fisheries, with one less factory than in 1897, show a gain of \$455,693 in the value of products in 1901, the value being \$362,032 in 1897 and \$817,725 in 1901. This large gain may in part be accounted for by the higher prices received for the products and in part by the increased catch of 115,504,331 menhaden, the catch of 1897 numbering 263,203,000 fish and that of 1901 378,727,331 fish. During the past few years factories have been extensively enlarged and improved and new and improved machinery has been introduced. The increase in steamers was 7, in purse seines 15, and in vessel and shore employees 407. Menhaden were found fairly plentiful, and the season on the whole was a satisfactory one.

The manufactured products of the menhaden fisheries amounted to 21,130 tons of dry scrap, 10,591 tons of acidulated scrap, and 723,215 gallons of oil. This business gives employment on vessels and in factories to 1,577 persons, the factory employees receiving \$92,308 in wages during 1901.

| Items. | No. | Value. | Items. | No. | Value. |

Table showing the extent of the menhaden industry of Virginia in 1901.

WHOLESALE FISHERY TRADE.

The wholesale trade in fishery products of the State was represented by 80 firms in 1901 and 56 in 1897, a gain of 24. Of the 80 firms, 67 were engaged in the oyster business, most of them, more or less extensively, from the planting of seed oysters to the gathering, opening, and distribution of the marketable crop to all sections of the country. This branch of business shows many changes and improvements and has increased considerably in importance.

The wholesale trade in food-fish is carried on by a comparatively small number of firms. The fresh fish are handled chiefly during the early spring runs of migratory fish, the season being much earlier than for the same species in northern waters. This early spring catch has a wide range of distribution. The only cured fish marketed are salted alewives.

The total number of employees in the wholesale firms was 4,132, the larger portion of whom were engaged in the opening of oysters. The wholesale firms paid in 1901 \$701,807 in wages, most of which went to oystermen for their eight months' work.

Reference has been made to an endless-chain scraper for removing oyster shells from the shucking rooms. This device is employed by Messrs. J. S. Darling & Son, of Hampton, one of the largest firms in Virginia, and has resulted in saving much time, labor, and expense. The old and expensive method of removing shells by shovels and wheelbarrows is still practiced by all of the other firms.

PAMPHLETS.

Serial No.

- Report of the Commissioner for the year ending June 30, 1901, including the reports of divisions of fish-culture, scientific inquiry, and fisheries, by George M. Bowers. Report for 1901, pp. 1-170, plates 1-5. 1902.
 Publications of the United States Commission of Fish and Fisheries available for distribution on December 1, 1901. Report for 1901, pp. 177-192. 1902.
 Notes on the fishes and mollusks of Lake Chautauqua, New York, by B. W. Evermann and E. L. Goldsborough. Report for 1901, pp. 169-175. 1902.
 The formulation of Pacte Rice June M. Ellipt. Bulletin for 1900, pp. 418-418.

- 484. The foraminifera of Porto Rico, by James M. Flint. Bulletin for 1900, pp. 415, 416. 1901.
- 485. Description of a new species of blenny from Japan, by Hugh M. Smith. Bulletin for 1901, pp. 93, 94. 1902. 486. List of species of fishes known to occur in the Great Lakes or their connecting
- waters, by Barton Warren Evermann. Bulletin for 1901, pp. 95, 96. 1902.
- 487. Preservation of fishery products by drying and dry-salting, by Charles H. Stevenson. Bulletin for 1898, pp. 389-424. 1902.
- 488. Preparation of fish eggs for food, by Charles H. Stevenson. Bulletin for 1898, pp. 541-548. 1902.
- 489. Refrigeration, or preservation by low temperature, by Charles H. Stevenson. Bulletin for 1898, pp. 358-388. 1902.
- 490. Preservation of fishery products by smoking, by Charles H. Stevenson. Bul-letin for 1898, pp. 474-506. 1902.
- 491. Notes on the tagging of four thousand adult cod at Woods Hole, Mass., by Hugh M. Smith. Report for 1901, pp. 193–208. 1902.
- 492. Notes on the silversides of the genus Menidia of the east coast of the United States, with descriptions of two new subspecies, by W. C. Kendall. Report for 1901, pp. 241-267. 1902. 493. Note on the Scotch methods of smoking haddocks, by Hugh M. Smith. Report
- for 1901, pp. 269-271. 1902.
- 494. Notes on the fishes of Lake Ontario. An annotated list of the fishes known to occur in Lake Champlain and its tributary waters. An annotated list of the fishes known to occur in the St. Lawrence River, by B. W. Evermann and W. C. Kendall. Report for 1901, pp. 209-240. 1902.

- 495. A report on fishes collected in Mexico and Central America, with notes and descriptions of five new species, by B. W. Evermann and E. L. Goldsborough. Bulletin for 1901, pp. 137-159. 1902.
- 496. The organic constituents of the scales of fish, by E. H. Green and R. W. Tower. Bulletin for 1901, pp. 97-102. 1902.
- 497. The reactions of copepods to various stimuli and the bearing of this on daily depth migrations, by G. H. Parker. Bulletin for 1901, pp. 103-123. 1902. 498. The gas in the swim-bladder of fishes. Biliary calculi in the squeteague, by
- R. W. Tower. Bulletin for 1901, pp. 125-135, plate xxi. 1902.
- 499. Description of a new species of shad (Alosa ohiensis), with notes on other foodfishes of the Ohio River, by Barton Warren Evermann. Report for 1901, pp. 273-288. 1902.
- 500. The reproductive period in the lobster, by Francis H. Herrick. Bulletin for 1901, pp. 161-166. 1902.
- 501. Notes on five food-fishes of Lake Buhi, Luzon, Philippine Islands, by Hugh M. Smith. Bulletin for 1901, pp. 167–171, plate 22. 1902. 502. Marine protozoa from Woods Hole, by Gary N. Calkins. Bulletin for 1901, pp.
- 413-468. 1902.
- 503. Notes on a species of barnacle (*Dichelaspis*) parasitic on the gills of edible crabs, by Robert E. Coker. Bulletin for 1901, pp. 399–412. 1902. 504. The fishes and fisheries of the Hawaiian Islands. A preliminary report, by
- D. S. Jordan and B. W. Evermann. Commercial fisheries of the Hawaiian Islands, by J. N. Cobb. Report for 1901, pp. 353-499, plates 21-27. 1902. 505. Notes on the fisheries of the Pacific Coast in 1899, by William A. Wilcox.
- Report for 1901, pp. 501-574, plates 28, 29. 1902. 506. Statistics of fisheries of the Great Lakes. Report for 1901, pp. 575-657. 1902.
- 507. Statistics of the fisheries of the Mississippi River and tributaries. Report for 1901, pp. 659-740. 1902
- The Pan-American Exposition. Report of representative of the U. S. Fish Commission, by W. de C. Ravenel. Report for 1901, pp. 289-351, pls. 6-20. 1902.
 Notes on the boats, apparatus, and fishing methods employed by the Albatross, by the South Sea Islands, and the results of fishing trials by the Albatross, by
- A. B. Alexander. Report for 1901, pp. 741–829, plates 30–37. 1902.
 510. The salmon and salmon fisheries of Alaska. Report of the Alaskan salmon investigations of the United States Fish Commission steamer Albatross in 1900 and 1901, by Jefferson F. Moser. Bulletin for 1901, pp. 173-398 and 399-401, plates t-xliv, plate A, and charts A, B. 1902. 511. Observations on the herring fisheries of England, Scotland, and Holland, by
- Hugh M. Smith. Bulletin for 1902, pp. 1-16, plates 1 and 2. 1903.
- 512. Japanese oyster culture, by Bashford Dean. Bulletin for 1902, pp. 17-37, plates 3–7. 1903.
- 513. The habits and culture of the black bass, by Dwight Lydell. Bulletin for 1902, pp. 39-44, plate 8. 1903. 514. Hearing and allied senses in fishes, by G. H. Parker. Bulletin for 1902, pp.
- 45-64, plate 9. 1903.
- 515. Natural history of the quinnat salmon. A report on investigations in the Sacramento River, 1896-1901, by Cloudsley Rutter. Bulletin for 1902, pp. 65-141, plates 10-18. 1903.
- 516. Notes on fishes from streams and lakes of northeastern California not tributary to the Sacramento Basin, by Cloudsley Rutter. Bulletin for 1902, pp. 145 - 148.1903.
- 517. Breeding habits of the yellow cat-fish, by Hugh M. Smith and L. G. Harron. Bulletin for 1902, pp. 151-154. 1903.
- 518. The destruction of trout fry by hydra, by A. E. Beardsley. Bulletin for 1902, pp. 157-160. 1903.
- 519. Artificial propagation of the salmons of the Pacific coast. Revised edition of Fish Manual, pp. 1–15, plates 3–10. 1903.
- 520. Artificial propagation of the lake trout, grayling, and white-fish. Revised edition of Fish Manual, pp. 91-120, plates 30-39. 1903.
- 521. Artificial propagation of the shad and pike perch. Revised edition of Fish Manual, pp. 121-145 and 165-179, plates 40-46 and 51-52. 1903.
- 522. Artificial propagation of marine species of fishes. Revised edition of Fish Manual, pp. 195-238, plates 54-63. 1903.
- 523. Descriptions of new genera and species of fishes from the Hawaiian Islands, by
- D. S. Jordan and B. W. Evermann. Bulletin for 1902, pp. 161–208. 1903. 524. Report of the Commissioner for the year ending June 30, 1902, including the reports of divisions of fish culture, scientific inquiry, and fisheries, by George M. Bowers. Report for 1902, pp. 1–160, plates 1–5. 1903.

The following are in press and will soon be available:

- 525. Descriptions of a new genus and two new species of fishes from the Hawaiian Islands, by David Starr Jordan and Barton Warren Evermann. Bulletin for 1902, pp. 209-210. 1903.
- 526. The fresh-water fishes of western Cuba, by Carl H. Eigenmann. Bulletin for 1902, pp. 211-236, plates 19-21. 1903.
- 527. The organ and sense of taste in fishes, by C. Judson Herrick. Bulletin for 1902, pp. 237-272. 1903.
- Rotatoria of the United States. II.—A monograph of the *Rattulidæ*, by H. S. Jennings. Bulletin for 1902, pp. 273–352, plates 1–xv. 1903.
 The plankton algae of Lake Erie, with special reference to the *Chlorophyceæ*, by
- Julia W. Snow. Bulletin for 1902, pp. 369-394, plates 1-1v. 1903.
- 530. Description of a new species of darter from Tippecanoe Lake, by William J. Moenkhaus. Bulletin for 1902, pp. 395-398. 1903.
- 531. Notes on some fresh-water fishes from Maine, by W. C. Kendall. Bulletin for 1902, pp. 353-368. 1903.
- 532. Habits of some of the commercial cat-fishes, by W. C. Kendall. Bulletin for 1902, pp. 399-409. 1903.
- 533. A more complete description of Bacterium trutta, by M. C. Marsh. Bulletin for 1902, pp. 411-416, plates 1 and 11. 1903.
- 534. Report on collections of fishes made in the Hawaiian Islands, with descriptions of new species, by Oliver P. Jenkins. Bulletin for 1902, pp. 417–511, plates 1-1v. 1903.
- 535. The sponge fishery of Florida in 1900, by J. N. Cobb. Report for 1902, pp. 161-175, plates 6-9. 1903.
- 536. Aquatic products in arts and industries, by C. H. Stevenson. Report for 1902, pp. 177–279, plates 10–25. 1903.
- 537. The utilization of the skins of aquatic animals, by C. H. Stevenson. Report for 1902, pp. 281–352, plates 26–38. 1903. 538. List of the common names of the basses and sun-fishes, by Hugh M. Smith.
- Report for 1902, pp. 353-366. 1903.
- 539. The fisheries and fish trade of Porto Rico, by W. A. Wilcox. Report for 1902, pp. 367-395. 1903.
- 540. Statistics of the fisheries of the Middle Atlantic States. Report for 1902, pp. 433-540. 1903.
